Groundwater Storage

Groundwater Storage Capacity. The total storage capacity is estimated at 264,000 af (Panaro 2000; VCPWA 2002).

Groundwater in Storage. Unknown.

Groundwater Budget (Type A)

Estimates of recharge include underflow of 1,100 af/yr and irrigation return of less than 100 af/yr (Panaro 2000). Extractions are estimated to be less than 400 af/yr (Panaro 2000).

Groundwater Quality

Characterization. Groundwater in the basin is sodium bicarbonate in character. Water from 2 public supply wells has an average TDS content of 772 mg/L in the basin with a range from 760 to 784 mg/L. However, TDS content can range from 1,100 to 3,000 mg/L during extended dry spells (VCPWA 1996).

Impairments. Hydrogen sulfide gas has been reported in the water, particularly during periods when water levels are lowest (DWR 1959). Oil has also been found in the water (DWR 1959). High sulfate and nitrate minerals are common along the shallow alluvium drainage courses where most remaining water wells are found (VCPWA 1996).

California's Groundwater Update 2020 (Bulletin 118)

2 Followers

California's Groundwater Update 2020 (CalGW) is California's foremost technical publication on groundwater in the state of California. CalGW, formally known as Bulletin 118, is legislatively mandated by Water Code 12924 to be updated every 5 years by the California Department of Water Resources.

This dataset includes the full publication of CalGW - Update 2020, a link to the new California's Groundwater Live (https://sgma.water.ca.gov/CalGWLive/) platform and all supporting data used in the creation of the report which was finalized on November 16, 2021. CalGW - Update 2020 consists of an Executive Summary (Highlights) and seven chapters commonly referred to as the Statewide Report. Due to the large file sizes, the Update has been broken into multiple pdf documents for the ease of downloading these large files.

For more information on California's Groundwater (Bulletin 118) including historical publications please visit California's Groundwater (Bulletin 118) Open Data Page (https://data.cnra.ca.gov/dataset/california-s-groundwater-bulletin-118-archive).

RE: Oxnard Subbasin – 2020 Groundwater Sustainability Plan

Dear Kimball Loeb,

The Department of Water Resources (Department) has evaluated the groundwater sustainability plan (GSP) submitted for the Oxnard Subbasin and has determined the GSP is approved. The approval is based on recommendations from the Staff Report, included as an exhibit to the attached Statement of Findings, which describes that the Oxnard Subbasin GSP satisfies the objectives of the Sustainable Groundwater Management Act (SGMA) and substantially complies with the GSP Regulations. The Staff Report also proposes recommended corrective actions that the Department believes will enhance the GSP and facilitate future evaluation by the Department. The Department strongly encourages the recommended corrective actions be given due consideration and suggests incorporating all resulting changes to the GSP in future updates.

Recognizing SGMA sets a long-term horizon for groundwater sustainability agencies (GSAs) to achieve their basin's sustainability goals, monitoring progress is fundamental for successful implementation. GSAs are required to evaluate their GSPs at least every five years and whenever the Plan is amended, and to provide a written assessment to the Department. Accordingly, the Department will evaluate approved GSPs and issue an assessment at least every five years. The Department will initiate the first five-year review of the Oxnard Subbasin GSP no later than January 13, 2025.

Please contact Sustainable Groundwater Management Office staff by emailing sgmps@water.ca.gov if you have any questions about the Department's assessment or implementation of your GSP.

Thank You,

_____

Paul Gosselin
Deputy Director for Sustainable Groundwater Management

Attachment:

1. Statement of Findings Regarding the Approval of the Oxnard Subbasin Groundwater Sustainability Plan

DocuSign Envelope ID: 5B9B76E4-E867-4025-B4BA-45E1F1AC59D0

STATE OF CALIFORNIA
DEPARTMENT OF WATER RESOURCES

STATEMENT OF FINDINGS REGARDING THE APPROVAL OF THE OXNARD SUBBASIN GROUNDWATER SUSTAINABILITY PLAN

The Department of Water Resources (Department) is required to evaluate whether a submitted groundwater sustainability plan (GSP or Plan) conforms to specific requirements of the Sustainable Groundwater Management Act (SGMA or Act), is likely to achieve the sustainability goal for the basin covered by the Plan, and whether the Plan adversely affects the ability of an adjacent basin to implement their GSP or impedes achievement of sustainability goals in an adjacent basin. (Water Code § 10733.) The Department is directed to issue an assessment of the Plan within two years of its submission. (Water Code § 10733.4.) This Statement of Findings explains the Department's decision regarding the Plan submitted by the Oxnard Subbasin (Subbasin No. 4-004.02).

Department management has reviewed the Department Staff Report, entitled Sustainable Groundwater Management Program Groundwater Sustainability Plan Assessment Staff Report, attached as Exhibit A, recommending approval of the GSP. Based on its review of the Staff Report, Department management is satisfied that staff have conducted a thorough evaluation and assessment of the Plan and concurs with staff's recommendation and all the recommended corrective actions. The Department thus approves the Plan based on the Staff Report and the findings contained herein.

A. The Plan satisfies the required conditions as outlined in § 355.4(a) of the GSP Regulations (23 CCR § 350 et seq.):

    1. The Plan was submitted to the Department on January 13, 2020, and thus within the statutory deadline of January 31, 2020. (Water Code § 10720.7(a)(1); 23 CCR § 355.4(a)(1).)

    2. The Plan is complete, meaning it includes the information required by the Act and the GSP Regulations sufficient to warrant a thorough evaluation by the Department. (23 CCR § 355.4(a)(2).)

    3. The Plan covers the entire Subbasin. (23 CCR § 355.4(a)(3).)

B. The Plan conforms with Water Code §§ 10727.2 and 10727.4 in the Act and substantially complies with the GSP Regulations. It is likely to achieve the sustainability goal for the Subbasin. In making this determination, the Department considered the following:

DocuSign Envelope ID: 5B9B76E4-E867-4025-B4BA-45E1F1AC59D0

1. The Plan's goal to improve groundwater levels to prevent seawater intrusion and its associated impacts related to groundwater storage, groundwater quality, and subsidence beyond 2015 conditions is reasonable and consistent with SGMA and the GSP Regulations. The Plan relies on credible information and science to sufficiently detail the hydrogeologic conceptual model, groundwater conditions, and water budget for the Subbasin, which provides a reasonable assessment of overdraft and serves as the sufficient basis for defining and assessing reasonable sustainable management criteria and projects and management actions.

2. The Plan identifies data gaps exist and describes reasonable measures to eliminate those data gaps. The Department recommends the agencies investigate further the hydraulic connectivity between the surface water bodies, semi-perched aquifer, and principal aquifers to reduce the uncertainty regarding the impacts groundwater extraction has on surface water and beneficial uses and users of surface water. Notwithstanding this recommendation, the Department finds that, at this time, the GSP contains a sufficient understanding of the groundwater conditions in the Subbasin and that implementation of the Plan during the collection and evaluation of additional information is not likely to cause serious or irreparable harm.

3. The projects and management actions designed to eliminate overdraft by increasing surface water supplies and decreasing groundwater production demand, if implemented in a reasonable and timely manner, will likely achieve the sustainability goal defined for the Subbasin.

4. The Plan provides a detailed explanation of how the varied interests of groundwater uses and users in the Subbasin were considered in developing the sustainable management criteria and how those interests would be impacted by the chosen minimum thresholds.

5. The Oxnard Subbasin GSP will not adversely impact the ability of the adjacent basins to be operated sustainably and will not impede the adjacent basins' ability to achieve their respective sustainability goals. Fox Canyon Groundwater Management Agency (Agency) took a regional approach to determine the combined sustainable yield of the Subbasin and adjacent Pleasant Valley Basin and Las Posas Subbasin, and then determined the sustainable yield for each groundwater subbasin. The minimum thresholds for each respective groundwater sustainability plan were established with consideration for the sustainability goals of the

DocuSign Envelope ID: 5B9B76E4-E867-4025-B4BA-45E1F1AC59D0

adjacent basins and to operate each groundwater basin within its sustainable yield.

6. The Agency, along with other local agencies have implemented numerous projects and management actions to address groundwater conditions in the Subbasin. The Agency's legal authority and history of managing groundwater provides a reasonable level of confidence that the Agency, Camrosa Water District-Oxnard Subbasin GSA, and County of Ventura GSA (collectively, the GSAs) have the legal authority and financial resources necessary to implement the Plan.

7. Through review of the Plan and public comments, the Department determines that the GSAs adequately responded to comments that raised credible technical or policy issues with the Plan, sufficient to warrant approval of the Plan at this time. The Department also notes that the recommended corrective actions included in the Staff Report are important to addressing certain technical or policy issues that were raised and, if not addressed before future, subsequent plan evaluations, may preclude approval of the Plan in those future evaluations.

C. In addition to the grounds listed above, DWR also finds that:

1. The Plan's compliance with the requirements of SGMA and substantial compliance with the GSP Regulations is congruent with the state policy regarding the human right to water (Water Code § 106.3). The Department developed its GSP Regulations consistent with and intending to further the policy through implementation of SGMA and the Regulations, primarily by achieving sustainable groundwater management in a basin. By ensuring substantial compliance with the GSP Regulations, the Department has considered the state policy regarding the human right to water. (23 CCR § 350.4(g).)

2. The Plan defines the undesirable result associated with depletion of interconnected surface water in the Oxnard Subbasin as a loss of groundwater dependent ecosystem (GDE) habitat. According to the Plan, because historical groundwater elevations have maintained the GDE in the past, the goal of maintaining groundwater levels at or above historical lows is, expected to protect against the undesirable result of depletion of interconnected surface water. The Department determines that in attempting to avoid the further loss of GDE habitat beyond any historic losses, the GSAs considered public trust resources in development of the Plan.

3. The California Environmental Quality Act (CEQA) does not apply to the Department's evaluation and assessment of the Plan.

Based on the above, the GSP submitted by the Agency for the Oxnard Subbasin is approved as being found to satisfy the requirements of SGMA and to be in substantial compliance with the GSP Regulations. Recommended corrective actions identified in the Staff Report will assist the Department's review of the Plan's implementation for consistency with SGMA and are thus recommended to be addressed in the GSP by the time of the Department's five-year review, which is set to begin on January 13, 2025, as required by Water Code § 10733.8.

Signed:

_____

Karla Nemeth, Director

Date: November 18, 2021

Exhibit A: Groundwater Sustainability Plan Assessment Staff Report – Oxnard Subbasin

State of California
Department of Water Resources
Sustainable Groundwater Management Program
Groundwater Sustainability Plan Assessment Staff Report

Groundwater Basin Name:	Oxnard Subbasin (Subbasin No. 4-004.02)
Submitting Agency:	Fox Canyon Groundwater Management Agency, Camrosa Water District, County of Ventura
Recommendation:	Approve
Date:	November 18, 2021

The Fox Canyon Groundwater Management Agency (FCGMA or Agency) Groundwater Sustainability Agency (GSA), Camrosa Water District-Oxnard Subbasin GSA, and County of Ventura GSA (collectively, the GSAs) submitted the Oxnard Subbasin (Subbasin) Groundwater Sustainability Plan (GSP or Plan) to the Department of Water Resources (Department) for evaluation and assessment as required by the Sustainable Groundwater Management Act (SGMA).[1] The GSP covers the entire Subbasin for the implementation of SGMA.

After evaluation and assessment, Department staff find the Oxnard Subbasin GSP includes the required components of a GSP, demonstrates a thorough understanding of the Subbasin based on the best available science and information, sets reasonable sustainable management criteria to prevent undesirable results as defined in the Plan, and proposes a set of projects and management actions that will likely achieve the sustainability goal defined for the Subbasin, as required by SGMA and the GSP Regulations.[2] Department staff will continue to monitor and evaluate the Subbasin's progress toward achieving the sustainability goal through annual reporting and future periodic GSP evaluation. Based on the current evaluation of the Plan, Department staff recommend approval of the Plan with recommended corrective actions described herein.[3] This assessment includes five sections:

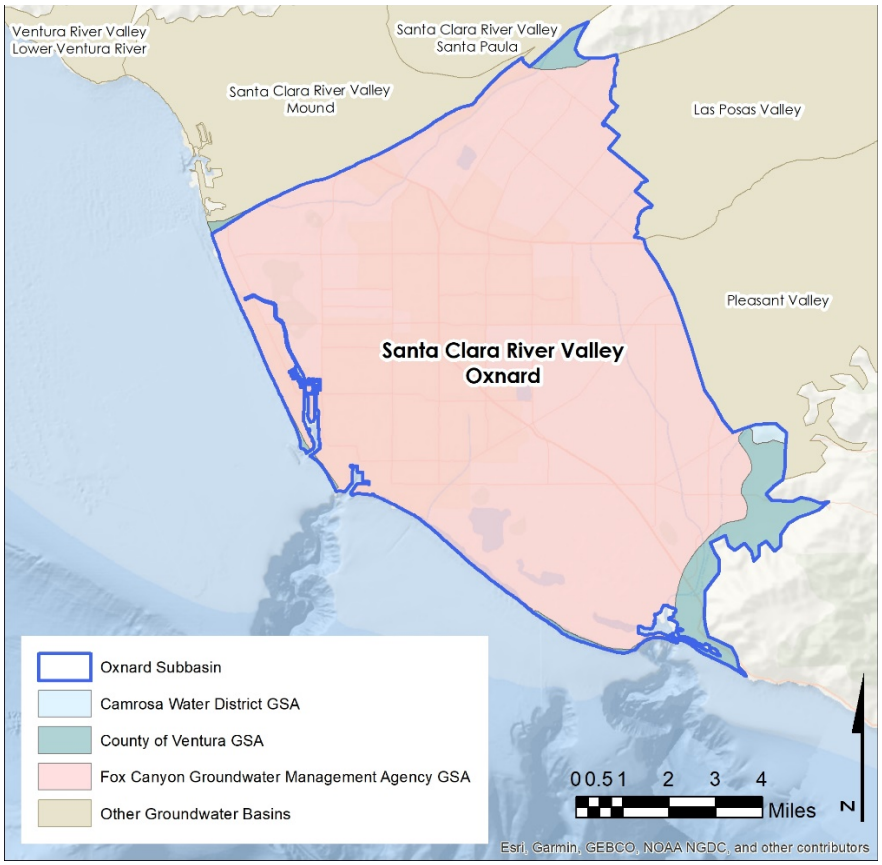
[1] Water Code § 10720 *et seq*.
[2] 23 CCR § 350 *et seq*.
[3] The Department recognizes that litigation, including a comprehensive adjudication of the Basin under Code of Civil Procedure section 830 et seq., has been filed. The filing of litigation does not alter or affect the Department's mandate to issue its assessment of the Agency's groundwater sustainability plan (GSP or Plan) for the basin within two years of its submission. (Water Code §10733.4(d).) The Department's assessment consists of a technical review of the submitted Plan, as required by SGMA and the GSP Regulations, and the filing of the adjudication or other litigation did not in any way influence or affect the Department's evaluation of the Plan. The Department expresses no opinion on the claims of the parties in the pending litigation involving the GSP or the groundwater basin. The role of a GSP in the adjudication process is addressed in Chapter 12 of SGMA (Water Code § 10737 et seq.).

- **Section 1 – Summary:** Provides an overview of the basin setting, GSP contents, and overview of the Department's assessment and recommendations.
- **Section 2 – Evaluation Criteria:** Describes the legislative requirements and the Department's evaluation criteria.
- **Section 3 – Required Conditions:** Describes the submission requirements, plan completeness, and basin coverage required for a GSP to be evaluated by the Department.
- **Section 4 – Plan Evaluation:** Provides a detailed assessment of the contents included in the GSP organized by each subarticle outlined in the GSP Regulations.
- **Section 5 – Staff Recommendation:** Includes the staff recommendation for the Plan and any recommended or required corrective actions, as applicable.

1 SUMMARY

A single GSP covering the entire Oxnard Subbasin was submitted to the Department by three GSAs on January 13, 2020. FCGMA is the lead GSA covering the majority of the Subbasin; a smaller portion of the Subbasin is covered by Camrosa Water District GSA, with remaining outlying areas covered by County of Ventura GSA.

The Oxnard Subbasin is a coastal groundwater basin located in Ventura County and is part of the Santa Clara River Valley Groundwater Basin (4-004) within the South Coast Hydrologic Region. The Subbasin is bounded by the Santa Monica Mountains to the southeast and by the Pacific Ocean to the west and southwest. Additionally, the Subbasin is bounded to the north by the Santa Paula Subbasin (4-004.04) and the Mound Subbasin (4-004.03)—both are part of Santa Clara River Valley Groundwater Basin—, and to the east by the Las Posas Valley Basin (4-008) and the Pleasant Valley Basin (4-006). The Santa Paula Subbasin is an adjudicated subbasin managed by the United Water Conservation District which is a court-appointed watermaster. The Oxnard Subbasin and the Pleasant Valley Basin are designated as critically overdrafted groundwater basins and were, therefore, required to be covered by GSPs submitted in 2020. The Las Posas Basin and the Mound Subbasin are designated as high-priority groundwater basins required to be covered by GSPs submitted in 2022. In 2020, the GSAs submitted GSPs covering the Oxnard Subbasin and the Pleasant Valley Basin, as well as a GSP covering the Las Posas Basin two years ahead of the statutory deadline of 2022. A vicinity map showing the Oxnard Subbasin, adjacent groundwater basins, and GSA boundaries is provided as Figure 1.



Water supply in the Subbasin comes from four sources: surface water, groundwater, recycled/reclaimed water, and imported water. The agricultural sector is the largest user of groundwater and accounts for 60 percent of the annual groundwater use. According to the GSP, the Subbasin's main land uses are agriculture and urban uses, each covering 47 percent of land area. The remaining land use is categorized as open space or water.

According to the GSP, seawater intrusion has been observed since the 1930s, and continues to be an issue due to ongoing conditions of groundwater overdraft. The current extent of seawater intrusion appears to reach as much as three miles inland. The Agency also recognizes seawater intrusion is one of the sources of water quality problems in the Subbasin that has resulted in higher concentrations of total dissolved solids (TDS) and chloride in the coastal area.

FCGMA has been implementing groundwater management actions since it was formed by the California Legislature in 1982. As examples, the Agency has instituted ordinances and programs that require groundwater extraction reporting and extraction fees, implemented a groundwater storage credit program, and approved a resolution through which recycled water discharged to Conejo Creek is delivered in lieu of groundwater pumping. Furthermore, local agencies such as United Water Conservation District

(UWCD), the City of Oxnard, and Calleguas Municipal Water District (CMWD) have implemented water supply projects that contributed new water sources in the Subbasin for municipal use, industrial use, agricultural use, and groundwater recharge to offset groundwater production, limit the decline in storage, and alleviate seawater intrusion. The GSP states that a history of interagency collaboration has resulted in the implementation of various conjunctive use programs which contributed to the groundwater elevation recovery in the 1990s. The Agency intends to implement the GSP alongside existing and planned conjunctive use programs in the Subbasin.

The GSP describes many existing surface water and groundwater monitoring programs in the Subbasin administered by other agencies such as the United States Geological Survey (USGS), Ventura County Watershed Protection District, UWCD, and CMWD. Groundwater quality in the Subbasin is monitored by multiple state and local agencies for various programs. The data provided by these monitoring programs and other investigations conducted in the Subbasin since the 1930s have been used to understand the groundwater conditions and develop sustainable management criteria for the GSP. FCGMA intends to continue to rely on groundwater elevation data collected by the Ventura County Watershed Protection District to assess the groundwater conditions for GSP annual reports and the 5-year GSP evaluations.

The sustainability goal for the Subbasin is to "increase groundwater elevations inland of the Pacific coast, to prevent landward migration of the 2015 saline water impact front,[5] and to prevent net seawater intrusion in the Upper Aquifer System and the Lower Aquifer System." As stated in the GSP, seawater intrusion is the primary sustainability indicator in the Oxnard Subbasin and sustainable management criteria were established based on information gathered over several decades from the monitoring programs investigations described above and with input from beneficial users of groundwater in the Subbasin. The GSPs of the neighboring Pleasant Valley Basin and Las Posas Basin were also developed by FCGMA, demonstrating a regional approach.

The GSP will use groundwater levels as a proxy to manage all applicable sustainability indicators and establishes sustainable management criteria that aim to either significantly improve groundwater conditions or not worsen them. For instance, minimum thresholds for seawater intrusion aim to limit net landward migration of the 2015 saline water impact front beyond the already impacted area while the measurable objectives aim to halt seawater flow into and freshwater flow out of the Upper Aquifer System or the Lower Aquifer System. Similarly, the expansion of areas impacted by degraded water quality that limit beneficial uses of groundwater is defined as an undesirable result. To manage depletions of interconnected surface water, the GSP establishes management criteria for the Oxnard aquifer which underlies and, as the GSAs claim, supports groundwater

[5] The GSP uses a term "2015 saline water impact front" to describe the 2015 extent of the seawater intrusion in the Oxnard Subbasin. The area of the Subbasin impacted by chloride concentrations greater than 500 milligrams per liter in 2015 is referred to as the saline water impact area. The Agency's reasoning to use the term saline water impact front rather than seawater intrusion is to reflect all potential sources of chloride to the aquifer, which are not limited to seawater.

elevations in the shallowest aquifer. The shallowest aquifer, locally referred to as the semi-perched aquifer, supports groundwater dependent ecosystems (GDEs) but is not considered a principal aquifer due to low groundwater production in the basin. The GSP proposes to continue monitoring the semi-perched aquifer to evaluate the depletion of interconnected surface water. The GSP recognizes significant and unreasonable lowering of groundwater levels and reduction of groundwater storage has occurred historically or is currently occurring in the Subbasin and defines the groundwater condition related to significant and unreasonable seawater intrusion.

To meet the sustainability goal of the Subbasin, the GSP proposes to implement a series of projects and management actions. Four proposed projects are related to the expansion of current water supply and groundwater recharge, and one project relates to temporary agricultural land fallowing. The GSP identifies two management areas that are vulnerable to seawater intrusion and chronic decline of groundwater levels. Management actions proposed to protect these vulnerable areas include reducing groundwater production and limiting the transfer of pumping allocations; FCGMA has the legislative authority to restrict groundwater production and conducted a pilot program for limiting transfer pumping allocations in 2019. The GSP acknowledges that the current revenue generated from pumpers of the Subbasin through extraction and sustainability fees would not be enough to fund the projects and management actions and, therefore, the Agency intends to increase the sustainability fee and impose a replenishment fee.

After reviewing the GSP, Department staff conclude that the best available science and information were relied on to analyze and describe the GSP elements, including the hydrogeologic conceptual model (HCM), groundwater conditions, and water budgets. The GSP has effectively identified where the data gaps exist. For example, one of the data gaps identified is the limited understanding of the extent and location of hydraulic connectivity between surface water bodies and the semi-perched and principal aquifers. Department staff believe that the GSA's further investigation of the hydraulic connectivity between surface water bodies and groundwater will improve the understanding of the impact(s) of groundwater production on the related sustainability indicators.

Department staff believe the GSP's goal to improve groundwater levels to prevent seawater intrusion and its associated impacts related to groundwater storage, groundwater quality, and subsidence beyond 2015 conditions are reasonable and consistent with SGMA and the GSP Regulations. The GSP proposes mitigating overdraft by implementing various projects and management actions, including reducing groundwater production and augmenting water supplies. As stated earlier, the Agency's primary management action is to implement pumping reductions, for which it has legislative authority.

The GSP's projects and management actions are an integral component for achieving the sustainability goal for the Subbasin; therefore, Department staff will monitor the progress and performance of these actions through annual reporting and five-year GSP updates (at a minimum). While the Plan does not include specific implementation details

regarding projects and management actions, Department staff find the overall approach described in the GSP to mitigate overdraft is reasonable, and if the proposed projects and management actions are implemented in a reasonable and timely manner, the GSP is likely to achieve the sustainability goal of the Subbasin.

For the reasons outlined above, Department staff recommend approval of the Oxnard Subbasin GSP. The GSP identifies several data gaps (e.g., HCM, interconnected surface water, and monitoring networks), which Department staff agree should be addressed. Department staff have also identified additional recommended corrective actions that should be considered by the GSAs for the first periodic evaluation of its GSP (see Section 5). Addressing these recommended corrective actions will be critical for the GSAs to demonstrate, on an ongoing basis, that implementation of the GSP is progressing toward achieving the sustainability goal.

2 EVALUATION CRITERIA

The GSAs submitted a single GSP to the Department to evaluate whether the Plan conforms to SGMA's requirements[6] and is likely to achieve the sustainability goal for the Oxnard Subbasin.[7] To achieve the sustainability goal for the Subbasin, the GSP must demonstrate that implementation of the Plan will lead to sustainable groundwater management, which means the management and use of groundwater in a manner that can be maintained during the planning and implementation horizon without causing undesirable results.[8] Undesirable results are defined quantitatively by the GSA(s).[9] The Department is also required to evaluate whether the GSP will adversely affect the ability of an adjacent basin to implement its GSP or achieve its sustainability goal.[10]

For the GSP to be evaluated by the Department, it must first be determined that the Plan was submitted by the statutory deadline,[11] and that it is complete and covers the entire Subbasin.[12] If these conditions are satisfied, the Department evaluates the Plan to determine whether it complies with SGMA and substantially complies with the GSP Regulations.[13] "Substantial compliance means that the supporting information is sufficiently detailed and the analyses sufficiently thorough and reasonable, in the judgment of the Department, to evaluate the Plan, and the Department determines that any discrepancy would not materially affect the ability of the Agency to achieve the sustainability goal for the basin, or the ability of the Department to evaluate the likelihood of the Plan to attain that goal."[14]

When evaluating whether the Plan is likely to achieve the sustainability goal for the Subbasin, Department staff reviewed the information provided and relied upon in the GSP for sufficiency, credibility, and consistency with scientific and engineering professional standards of practice.[15] The Department's review considers whether there is a reasonable relationship between the information provided and the assumptions and conclusions made by the GSAs, including whether the interests of the beneficial uses and users of groundwater in the Subbasin have been considered; whether sustainable management criteria and projects and management actions described in the Plan are commensurate with the level of understanding of the basin setting; and whether those projects and management actions are feasible and likely to prevent undesirable results.[16]

[6] Water Code §§ 10727.2, 10727.4.
[7] Water Code § 10733(a).
[8] Water Code § 10721(v).
[9] 23 CCR § 354.26 *et seq*.
[10] Water Code § 10733(c).
[11] 23 CCR § 355.4(a)(1).
[12] 23 CCR §§ 355.4(a)(2), 355.4(a)(3).
[13] 23 CCR § 350 *et seq*.
[14] 23 CCR § 355.4(b).
[15] 23 CCR § 351(h).
[16] 23 CCR § 355.4(b)(1), (3), (4) and (5).

The Department also considers whether the GSA(s) has the legal authority and financial resources necessary to implement the Plan.[17]

To the extent overdraft is present in a basin, the Department evaluates whether the Plan provides a reasonable assessment of the overdraft and includes reasonable means to mitigate the overdraft.[18] The Department also considers whether the Plan provides reasonable measures and schedules to eliminate identified data gaps.[19] Lastly, the Department's review considers the comments submitted on the Plan and evaluates whether the GSA(s) adequately responded to the comments that raise credible technical or policy issues with the Plan.[20]

The Department is required to evaluate the Plan within two years of its submittal date and issue a written assessment of the Plan.[21] The assessment is required to include a determination of the Plan's status.[22] The GSP Regulations provide three options for determining the status of a Plan: Approved,[23] Incomplete,[24] or Inadequate.[25]

Even when review indicates that the GSP satisfies the requirements of SGMA and is in substantial compliance with the GSP Regulations, the Department may recommend corrective actions.[26] Recommended corrective actions are intended to facilitate progress in achieving the sustainability goal within the basin and the Department's future evaluations, and to allow the Department to better evaluate whether the Plan adversely affects adjacent basins. While the issues addressed by the recommended corrective actions do not, at this time, preclude approval of the Plan, the Department recommends that the issues be addressed to ensure the Plan's implementation continues to be consistent with SGMA and the Department is able to assess progress in achieving the sustainability goal within the basin.[27] Unless otherwise noted, the Department proposes that recommended corrective actions be addressed by the submission date for the first five-year assessment.[28]

The staff assessment of the GSP involves the review of information presented by the GSA(s), including models and assumptions, and an evaluation of that information based on scientific reasonableness. The assessment does not require Department staff to recalculate or reevaluate technical information provided in the Plan or to perform its own geologic or engineering analysis of that information. The staff recommendation to approve a Plan does not signify that Department staff, were they to exercise the professional

judgment required to develop a GSP for the basin, would make the same assumptions and interpretations as those contained in the Plan, but simply that Department staff have determined that the assumptions and interpretations relied upon by the submitting GSA(s) are supported by adequate, credible evidence, and are scientifically reasonable.

Lastly, the Department's review and approval of the Plan is a continual process. Both SGMA and the GSP Regulations provide the Department with the ongoing authority and duty to review the implementation of the Plan.[29] Also, GSAs have an ongoing duty to reassess their plans, provide reports to the Department, and, when necessary, update or amend their plans.[30] The passage of time or new information may make what is reasonable and feasible at the time of this review to not be so in the future. The emphasis of the Department's periodic reviews will be to assess the progress toward achieving the sustainability goal for the basin and whether Plan implementation adversely affects the ability of adjacent basins to achieve their sustainability goals.

[30] Water Code §§ 10728 *et seq*, 10728.2.

3 REQUIRED CONDITIONS

A GSP, to be evaluated by the Department, must be submitted within the applicable statutory deadline. The GSP must also be complete and must, either on its own or in coordination with other GSPs, cover the entire basin. If corrective actions have been identified by the Department, in the context of an Incomplete assessment, the GSAs must also have sufficiently addressed those corrective actions within the period of time provided.

3.1 SUBMISSION DEADLINE

SGMA required basins categorized as high- or medium-priority as of January 1, 2017 and that were subject to critical conditions of overdraft to submit a GSP no later than January 31, 2020.[31]

The GSAs submitted their GSP on January 13, 2020, in compliance with the statutory deadline.

3.2 COMPLETENESS

GSP Regulations specify that the Department shall evaluate a GSP if that GSP is complete and includes the information required by SGMA and the GSP Regulations.[32]

The GSAs submitted an adopted GSP for the entire Subbasin. Department staff found the GSP to be complete and include the required information, sufficient to warrant an evaluation by the Department. The Department posted the GSP to its website on January 31, 2020.

3.3 BASIN COVERAGE

A GSP, either on its own or in coordination with other GSPs, must cover the entire basin.[33] A GSP that intends to cover the entire basin may be presumed to do so if the basin is fully contained within the jurisdictional boundaries of the submitting GSA(s).

The GSP intends to manage the entire Subbasin and the jurisdictional boundaries of the submitting GSA(s) cover the entire Oxnard Subbasin.[34] However, the GSP acknowledges that it uses the Subbasin boundary defined by the 2016 version of the Department's Bulletin 118 instead of the 2018 version to maintain consistency with the GSP's groundwater model. The GSP discusses the differences between the two boundary versions and concluded that the 2018 administrative modification to the Subbasin boundary had a limited impact on the water budget, from a sustainable management

[31] Water Code § 10720.7(a)(1).
[32] 23 CCR § 355.4(a)(2).
[33] Water Code § 10727(b), 23 CCR § 355.4(a)(3).
[34] Oxnard Subbasin GSP, Figure 1-2, p. 103.

perspective, because the change in Subbasin areas did not include or exclude representative monitoring sites or production wells and does not affect the groundwater model conditions and parameters.[35] Department staff generally agree with the GSP's statement that the boundary modification was primarily administrative and results in negligible changes to the water budget. Staff acknowledge that much of the groundwater model and the GSP were developed prior to the Department adopting the modified boundary and, therefore, find the Agency's approach to use the 2016 boundary to be reasonable and not likely to affect the Agency's ability to implement the GSP across the entire Subbasin.

[35] Oxnard Subbasin GSP, Section 1.3.1, p. 38-39.

4 PLAN EVALUATION

As stated in Section 355.4 of the GSP Regulations, a basin "shall be sustainably managed within 20 years of the applicable statutory deadline consistent with the objectives of the Act." The Department staff's evaluation of the likelihood of the GSP to attain the sustainability goal for the Subbasin is provided below.

4.1 ADMINISTRATIVE INFORMATION

The GSP Regulations require each GSP to include administrative information identifying the submitting agency, describing the plan area, and demonstrating the legal authority and ability of the submitting agency to develop and implement a plan for that area.[36]

4.1.1 Evaluation Summary

The detailed administrative information included in the GSP substantially complies with the requirements outlined in the GSP Regulations. The GSP adequately describes the Subbasin coverage by the three GSAs and the legal authority of the GSAs to manage groundwater within the Subbasin. The GSP provides detailed information on the various water resources management programs, monitoring programs, conjunctive-use programs, regulatory programs, urban water management plans, general plans, and additional plan elements that are relevant to sustainable groundwater management. The GSP also provides detailed information on FCGMA's past and current groundwater management activities in the Subbasin. Based on the information provided, Department staff conclude that the Agency's past and ongoing collaboration with local agencies to implement various water resources management programs demonstrate that the FCGMA, along with Camrosa Water District GSA and County of Ventura GSA, will likely continue to manage groundwater in the Subbasin to meet the requirements of SGMA.

The GSP sufficiently describes the geographic areas covered by the GSP, including the types of land use based on 2015 data, sources of water, and existing water resources management programs. The beneficial uses and users of groundwater in the Subbasin are adequately described, as well as how interested parties were consulted regarding the status and development of the GSP.[37] The GSP was developed through participation of other agencies and beneficial users and was revised and finalized based on the feedback received from the interested parties.

4.1.2 Agency Information

Three GSAs worked together to complete a single GSP for the Subbasin (Oxnard GSP). FCGMA is the lead GSA, which covers the majority (94.1 percent) of the Subbasin's geographical area. SGMA specifically permitted FCGMA to become the exclusive GSA

[36] 23 CCR § 354.2 *et seq*.
[37] Oxnard Subbasin GSP, Section 1.8, p. 73-77.

within its statutory boundary.[38] Formed as a special district in 1982 to manage groundwater, FCGMA has been collaboratively managing groundwater in the Subbasin for over three decades. The groundwater management activities include oversight of various water resources management programs such as groundwater storage and injection credits programs, extraction limitations, extraction surcharges, the prohibition of groundwater exports, and municipal, industrial, and agriculture allocation programs.[39] Camrosa Water District (CWD) GSA and County of Ventura - Oxnard Outlying Areas GSA cover areas of the Subbasin outside the jurisdiction of FCGMA.

The GSP describes the Agency's funding plans and the three types of costs associated with GSP implementation, consisting of basic operation costs, implementation costs, and project costs.[40] The GSP states that the Agency collects a groundwater extraction fee to fund its basic operations and collects a sustainability fee, which is expected to generate additional revenue to cover the implementation costs and a portion of the project costs. The GSP estimates that it will cost $21,265,000 per year to cover the project and water supply costs for the first five years of implementation. Because the Agency developed the GSPs for the adjacent Pleasant Valley and Las Posas basins, the GSP provides the Agency's estimated implementation cost for all three groundwater basins. Collectively, the implementation cost for all three basins is estimated to be $79,302,272 for the period of 2020 through 2040. Given FCGMA's legal authority and history of groundwater management, the Department staff are reasonably confident that the Agency has the means to generate financial resources to implement the GSP.

4.1.3 Description of Plan Area

The GSP shows that the three main types of land use in the Subbasin are agriculture (47 percent), urban (47 percent), and open space or water (6 percent).[41] The cities of Oxnard and Port Hueneme overlie the Subbasin. The cities of Ventura and Camarillo lie primarily outside the Subbasin; however, the cities' outer edges are crossed by the Subbasin boundary. Naval Base Ventura County is federal land, which occupies 10 percent of the Subbasin's area.

The beneficial users of groundwater are agricultural, municipal, industrial, and environmental users. The GSP states that approximately 60 percent of the groundwater is used by the agricultural sector, and the remaining 40 percent is used by other sectors. The GSP identifies GDEs as the primary environmental user of groundwater in the Subbasin.

The Oxnard Subbasin has a complex network of water supply, water management, and delivery projects, including diversions of Santa Clara River and Conejo Creek; importing

[38] Water Code § 10723(c)(1)(D).
[39] Oxnard Subbasin GSP, Section 1.4, p. 46-49, Table 1-11, p. 92-95.
[40] Oxnard Subbasin GSP, Section 1.2.6, p. 33-36, Section 5, 538-551.
[41] Oxnard Subbasin GSP, Table 1.8, p. 88.

water from the State Water Project and Metropolitan Water District; and various recycled and reclaimed water treatment programs.

The main sources of water in the Subbasin are surface water, groundwater, recycled/reclaimed water, and imported water. Diverted surface water from the Santa Clara River and Conejo Creek is used for managed aquifer recharge in spreading basins and for non-potable applications. Recycled water produced by the Advance Water Purification Facility is used for agriculture, whereas recycled water produced by the Hill Canyon Wastewater Treatment Plant is discharged into Conejo Creek and diverted for use in lieu of groundwater pumping.

Many of the existing monitoring programs, including groundwater level and groundwater quality monitoring, surface water quality monitoring, stormwater quality monitoring, precipitation monitoring, and streamflow monitoring, are administered by other agencies.[42] Few of the existing monitoring programs are overseen by FCGMA, who collect and analyze data for annual groundwater extraction and analyze water quality data to track the progress toward meeting Basin Management Objectives. The GSP states that these monitoring programs are anticipated to continue, and the data from these programs will continue to be used to assess groundwater conditions in the Subbasin. The GSP lists several existing groundwater management programs that operate in the Subbasin.[43] Programs include groundwater recharge projects, recycled water programs, a surface water diversion project, allocation programs, water conservation programs, groundwater storage and injection credit programs, prohibition of groundwater export, extraction limitation and surcharge programs, extraction fee and reporting programs, water credit transfer program, salinity management program and imported water program.

The GSP describes how the four existing urban water management plans (UWMP) may affect sustainable groundwater management within the Subbasin and how the GSP may impact the assumptions of these UWMPs.[44] The GSP also provides descriptions of existing conjunctive use programs and additional plan elements.[45] The GSP states that the three UWMP discussed as the additional plan elements do not interface with SGMA or affect the Subbasin's sustainability because the implementation agencies do not directly pump groundwater from the Subbasin. The GSP further states that Naval Base Ventura County groundwater use currently represents approximately 1 percent of groundwater pumped in the Oxnard Subbasin and Pleasant Valley Basin and may voluntarily agree to an allocation under the GSP less than its full federal reserved water rights.

The GSP discusses three general plans that are applicable in the Oxnard Subbasin.[46] The Agency is planning to coordinate with Ventura County on the next update of the

[42] Oxnard Subbasin GSP, Table 1-10 and Table 1-11, p. 91-95.
[43] Oxnard Subbasin GSP, Table 1-11, p. 92-95.
[44] Oxnard Subbasin GSP, Section 1.6.2, p. 57-65.
[45] Oxnard Subbasin GSP, Section 1.5, p. 49-52, Section 1.6.3, p. 65-69.
[46] Oxnard Subbasin GSP, Sections 1.6.1, p. 53-57.

general plan to ensure that the GSP and the general plan update are mutually consistent.[47] The GSP also states that the City of Oxnard's General Plan does not contain water supply assumptions, which would conflict with the sustainable management criteria or the projects and management actions proposed in Oxnard GSP. However, the City of Oxnard submitted a comment to the Department claiming that the GSP's statement is inaccurate because there are fundamental inconsistencies between the City's 2030 General Plan and the GSP. The City further states that water demand in the City could increase by 50 percent due to population growth, so the GSP's management action to reduce groundwater pumping by 40 percent is inconsistent with the City's growth assumptions, long-term strategy for groundwater management, water supply assumption, and the land use plan. Department staff encourage FCGMA to work with the City of Oxnard to rectify the difference in policies that could potentially impact SGMA implementation in the Subbasin.

4.1.4 Notice and Communication

The GSP describes notification and communication efforts made by the Agency during Plan development and includes a Public Outreach and Engagement Plan.[48] Parties who would be potentially affected by the use of groundwater use in the Subbasin are listed in the Plan as 1. Surface water suppliers, 2. Municipal well operators and water purveyors, 3. Agricultural, Domestic, and Environmental users, 4. Local land-use planning agencies, 5. The Federal government, and 6. Disadvantaged Communities (DACs).[49]

Based on the Agency governance structure provided in the GSP, most of these interested parties, along with agricultural groups, have direct representation through membership on the FCGMA Board. The GSP states that although environmental users, the U.S. Navy, and DACs do not have representation on the Agency board, they had various opportunities to participate in the GSP development process. For example, environmental user interests were represented through the appointment of an environmental representative on the Technical Advisory Group (TAG). Additionally, representatives from the DACs and the U.S. Navy participated in the Agency's public meetings and are on the list of interested parties who receive electronic newsletters regarding the status and development of the Oxnard GSP. The GSP also states that, in addition to the U.S. Navy's participation during public meetings, the Agency coordinated with the U.S. Navy during GSP development.

The Agency conducted over 100 public meetings and five public workshops to discuss the GSP between March 2015 and November 2019,[50] including a special TAG meeting to discuss potential GDEs.[51] During the TAG meeting, comments were accepted from the

[47] Oxnard Subbasin GSP, Sections 1.6.1, p. 54.
[48] Oxnard Subbasin GSP, Appendix B, p. 890-916.
[49] Oxnard Subbasin GSP, Section 1.8.2, p. 73-76.
[50] Oxnard Subbasin GSP, Table 1-12, p. 97-100.
[51] Oxnard Subbasin GSP, Section 1.8.2, p. 75.

public regarding potential impacts to surface water bodies. Additional means of outreach include a survey for input on sustainability indicators, a public call for project ideas for incorporation in the GSP, circulating electronic newsletters, and regularly posting updates on the Agency website. During GSP implementation, the Agency intends to use the same tools of communication that were used during GSP development. The opportunities and efforts regarding outreach, collaboration, and communication with interested parties are provided in the GSP.[52]

During GSP development, FCGMA received several written comment letters.[53] The GSP describes that, in consideration of some of these comments, the Agency completed an independent peer review of the numerical groundwater models, completed additional analysis for the water quality approach, and extended the timeline for completion of the GSP.[54]

Given the GSP's description of the Agency's robust engagement efforts with other agencies and interested parties throughout the GSP development process and its proposed commitment to continue with the same engagement mechanisms during GSP implementation, Department staff are satisfied that the GSP substantially complies with the requirements pertaining to Notice and Communication.[55]

4.2 Basin Setting

GSP Regulations require information about the physical setting and characteristics of the basin and current conditions of the basin, including a hydrogeologic conceptual model; a description of historical and current groundwater conditions; and a water budget accounting for total annual volume of groundwater and surface water entering and leaving the basin, including historical, current, and projected water budget conditions.[56]

4.2.1 Evaluation Summary

The description of the basin setting in the GSP substantially complies with the requirements outlined in the GSP Regulations. The GSP describes in sufficient detail the hydrogeologic conceptual model, groundwater conditions, and water budget for the Subbasin, which appear to be based on the best information and science available at the time the GSP was prepared. The GSP identifies data gaps in the basin setting and describes actions that could be taken to fill data gaps. Department staff find the descriptions of groundwater levels, groundwater in storage, seawater intrusion, and water quality sufficiently demonstrate that the Agency understands the groundwater conditions in the Subbasin.

[52] Oxnard Subbasin GSP, Appendix B, p. 890-916.
[53] Oxnard Subbasin GSP, Appendix A-5, p. 587-889.
[54] Oxnard Subbasin GSP, Section 1.8.4, p. 76.
[55] 23 CCR § 354.10.
[56] 23 CCR § 354.12 *et seq.*

The GSP includes historical, current, and projected water budget estimates for the Subbasin which were developed using a numerical model. The Agency used the water budgets to determine the historical and projected sustainable yield and overdraft. Department staff believe that the water budget components provided in the GSP were developed using the best available tools and information available at the time the GSP was prepared and substantially comply with the GSP Regulations. Overall, the GSP's description of the Subbasin's physical characteristics and current conditions is sufficient to serve as the basis for defining and assessing reasonable sustainable management criteria and projects and management actions.

4.2.2 Hydrogeologic Conceptual Model

The GSP identifies six aquifers in the Subbasin. Five of these aquifers are considered primary or principal aquifers in the GSP and are grouped into the Upper Aquifer System and the Lower Aquifer System. The Upper Aquifer System includes the Oxnard and Mugu aquifers and the Lower Aquifer System contains the Hueneme, Fox Canyon, and Grimes Canyon aquifers.[57] The GSP states that, in most of the Subbasin, a hydraulic connection exists between the Mugu aquifer in the Upper Aquifer System and the Hueneme aquifer in the Lower Aquifer System; the hydraulic connection between the Mugu and Hueneme aquifers is absent in the southwestern portion of the Subbasin, where seawater intrusion has affected the Mugu aquifer.[58] The GSP states that both of the aquifer systems in the Subbasin extend offshore and are believed to have direct hydraulic connection with the Pacific Ocean.

The GSP explains that the uppermost aquifer, referred to as the semi-perched aquifer, is excluded from the Upper Aquifer System and is not considered a primary aquifer because of limited groundwater production.[59] A clay layer separates the semi-perched aquifer from the underlying Oxnard aquifer.[60] The GSP states that the clay layer functions as an aquitard, restricting the flow of groundwater between the aquifers; however, water can still migrate vertically under conditions of differential head and through improperly abandoned wells.[61] The GSP states that both the semi-perched aquifer and the clay layer are absent in the Forebay area of the Subbasin, which makes the Forebay area the most desirable for groundwater recharge, but also the most vulnerable for contaminants to migrate into the principal aquifers.[62]

The Santa Clara River runs through the Subbasin and provides groundwater recharge to the Upper Aquifer System and the semi-perched aquifer. The Santa Clara River also delivers State Water Project water for managed aquifer recharge in spreading grounds

[62] Oxnard Subbasin GSP, Section 2.2, p. 118, Section 2.5, p. 192, Section 2.3.4.3, p. 153, Section 3.3.4.2, p. 414-415.

and irrigation for agricultural users.[63] Calleguas Creek also provides groundwater recharge to the semi-perched aquifer, but does not directly recharge the Upper Aquifer System due to a lack of hydraulic connectivity.[64] The GSP identifies potential recharge areas mainly located near or along the Santa Clara River and in sandy sediments along the northern coastal areas of the Subbasin.[65]

The Agency's understanding of the geographic, geologic, and structural settings along with other physical attributes (such as lateral and vertical boundaries) of the Subbasin, its aquifers, and aquitards are represented graphically and through written descriptions in the GSP. The GSP includes various maps such as surficial geology, cross-sections, rivers and drainages, impaired surface water bodies, water conveyance and treatment infrastructure, recharge basins, and stream gauges to thoroughly describe the hydrogeologic conceptual model and the supporting information as required by the GSP Regulations.

The GSP does identify data gaps in the hydrogeologic conceptual models as uncertainties associated with aquifer-specific data, the distinct sources of high TDS concentrations in the Lower Aquifer System, the relative impact of groundwater pumping in specific areas on seawater intrusion, and the interaction between the semi-perched aquifer and GDEs. The Plan states that these uncertainties are due to a lack of wells screened solely in a single aquifer and limited temporal and spatial distribution of the available monitoring wells.[66] Despite the uncertainties caused by limited data availability, in certain circumstances, Department staff find the Agency had credible data spanning several decades to rely on and uses the best available information to provide a sufficient understanding of the physical characteristics of the Subbasin, including the geologic and hydrogeologic conditions.

4.2.3 Groundwater Conditions

Hydrographs provided in the GSP for the five principal aquifers show groundwater level trends from the 1980s to 2015 with additional groundwater elevation data for the Oxnard aquifer dating as far back as the 1930s.[67] The hydrographs from all principal aquifers show a pattern of decline and recovery in groundwater elevation until the 1990s, followed by a significant recovery in the early 1990s that resulted in artesian conditions observed in wells screened in the western portions of the Oxnard aquifer.[68] The GSP states that the recovery in groundwater elevation was likely due to a combination of several wet years during the 1990s, the effects of management actions, and the construction of water conservation facilities in the 1980s and 1990s.

[63] Oxnard Subbasin GSP, Section 2.4.1.1, p. 165.

[66] Oxnard Subbasin GSP, Section 2.2.4, p. 128, Section 2.3.1.1, p. 130, Section 4.6.1, p. 485.
[67] Oxnard Subbasin GSP, Figure 2-9A – Figure 2-21, p. 241-267.
[68] Oxnard Subbasin GSP, Section 2.3, p. 132-141, Section 2.3, p. 139.

The hydrographs also show that the groundwater levels were relatively stable from 1990 to 2010 then experienced a significant decline after 2010. Between 2011 and 2015, groundwater elevations declined by up to 100 feet in some areas. Though the historical trends suggest groundwater levels in the Subbasin tend to decline during periods of drought and recover, groundwater elevations have not yet recovered from the drought beginning in 2011.[69] Some of the hydrographs show that the groundwater elevations have continued to decline after 2015. The Forebay area appears to be highly impacted by the recent drought, as the water level declines in the Oxnard and Mugu aquifers have been the most pronounced. Another area greatly affected by droughts appears to be the coastal Grimes Canyon aquifer, where groundwater elevations have remained below mean sea level since the 1990s.[70]

In addition to the hydrographs, groundwater elevation contour maps for principal aquifers are provided for 2015 fall and spring groundwater conditions. The GSP states that the groundwater elevations in all of the principal aquifers were higher than those in the underlying aquifers, resulting in a downward vertical gradient, with an exception in the Port Hueneme area where groundwater elevations in the Grimes Canyon aquifer are higher than those in the overlying Fox Canyon aquifer. The GSP does not explain the reason for this difference in vertical gradient in Port Hueneme. However, the GSP states that the vertical gradients along the coast are generally lower than they are inland.[71]

The UWCD used a numerical groundwater flow model to estimate the change in groundwater storage from 1986 to 2015 for the Subbasin.[72] The GSP states that the cumulative change in storage (i.e., the Upper Aquifer System and Lower Aquifer System were replenished by seawater) over this period was a net loss of approximately 101,400 acre-feet (i.e., an average decrease of 3,400 acre-feet per year).[73] The GSP states that the annual change in storage ranges from a maximum decrease of approximately 48,700 acre-feet during 1987 and a maximum increase of approximately 81,000 acre-feet during 2005.[74]

Without seawater intrusion (i.e., if the Upper Aquifer System and Lower Aquifer System were not replenished by seawater), the cumulative change in freshwater storage between 1986 and 2015 for the Subbasin was a loss of approximately 380,200 acre-feet (i.e., an average decrease of approximately 12,700 acre-feet per year).[75] The annual change of freshwater in storage ranges from a maximum increase of approximately 74,700 acre-feet in 2005 to a maximum decrease of approximately 73,500 acre-feet in 1990.[76] During

[75] Oxnard Subbasin GSP, Section 2.3.2, p. 143.
[76] Oxnard Subbasin GSP, Section 2.3.2, p. 143.

the model period, there was approximately 9,400 acre-feet per year of seawater intrusion into the principal aquifers of the Oxnard Subbasin.[77] The UWCD groundwater model estimates suggest that between 1985 and 2015, approximately 1,800 acre-feet per year of groundwater flowed to the Pacific Ocean from the semi-perched aquifer, which is not considered a principal aquifer.[78]

According to the GSP, seawater intrusion in the Subbasin was first observed in the 1930s and the impacted area continued to expand through the 1970s. Seawater intrusion into the Subbasin preferentially occurs near Port Hueneme and Point Mugu due to the direct contact and hydraulic connection of onshore freshwater aquifer units with deeply incised submarine canyons.[79] In Port Hueneme, which has groundwater elevations below sea level, the saline water impact front reached as much as three miles inland by the early 1980s. The GSP states that in the late 1970s and early 1980s, the area of the Upper Aquifer System affected by seawater intrusion was reduced due to the management actions by the Agency along with above-average rainfall. The historical progression of seawater intrusion from 1985 to 2015 in Upper Aquifer System and Lower Aquifer System are graphically presented in the GSP[80], which shows that seawater intrusion was mitigated in the Upper Aquifer System during the 1990s when a surface water diversion project was completed.[81] During this time, seawater intrusion began to affect the Lower Aquifer System. Between 2000 and 2012, there was no significant change in the extent of seawater intrusion. However, beginning in 2013, seawater intrusion has increased in both aquifer systems.[82]

The GSP uses the phrase “saline water impact area” to describe the area of the Subbasin impacted by chloride concentrations greater than 500 milligrams per liter and the phrase “saline water impact front” to describe the landward extent of the saline water impact area.[83] The Agency uses the phrase “saline water impact area”, rather than “seawater intrusion impact area”, to include other potential sources of chloride in the aquifer. The other contributors of salinity are identified as non-marine high-salinity connate water released during compaction of aquitards and older geologic formations beneath the freshwater aquifers, and vertical groundwater movement between major aquifers due to mergence between aquifers, and wells screened across multiple aquifers.[84] The areal extent of chloride concentration in all six aquifers and the current extent of saline water intrusion in the Upper Aquifer System and the Lower Aquifer System are shown on a

[83] Oxnard Subbasin GSP, Executive Summary, p. 17.
[84] Oxnard Subbasin GSP, Section 2.3.3.1, p. 144.

series of maps and a cross-section.[85] The GSP states that the chloride concentrations in wells near the coast are close to those of seawater and that the current area of seawater intrusion is smaller than the area of high chloride concentrations shown in maps because seawater intrusion is only one of the three reasons for the elevated salinity in the Subbasin.

The GSP identifies the primary reasons for degraded water quality as contaminated groundwater from the semi-perched aquifer, seawater intrusion, connate water from fine-grained lagoonal deposits, brines migrating via faults or upwelling from older geologic formations, mineral dissolution in groundwater, historical septic discharges, and agricultural fertilizer application practices.[86] The Agency has been conducting water quality monitoring and reporting to the Los Angeles Regional Water Quality Control Board (LARWQCB). The GSP discusses the elevated concentration of key constituents of concern for water quality and provides concentration maps that show elevated concentrations of TDS, sulfate, and boron are present throughout the basin, with a higher concentration of chloride near the coast and a higher concentration of nitrate near the Forebay area.[87]

The GSP states that during 2011 to 2015, TDS and chloride concentrations in the Lower Aquifer System were higher in the southern part of the Subbasin compared to the northern part. The primary areas of concern for groundwater quality degradation in the Subbasin are identified as the Forebay Management Area, the Saline Intrusion Management Area, and the Oxnard Pumping Depression Management Area.[88] The GSP also discusses groundwater quality impacts from other operations in the Subbasin, such as petroleum extraction and contaminated sites. However, the GSP concludes that the impact on groundwater quality from these sites is either not identified by beneficial users or the impacts are mitigated due to the presence of a confining layer. Furthermore, the Agency reviewed active contamination cases in GeoTracker and EnviroStor databases and concluded that existing groundwater contamination in the semi-perched aquifer do not pose a substantial threat to beneficial use of groundwater in the Upper Aquifer System and Lower Aquifer System.[89]

The GSP identifies three possible causes of land subsidence as groundwater pumping, petroleum reservoir compaction, and tectonic activity, but acknowledges groundwater pumping as the major cause of land subsidence in the Oxnard Subbasin. The GSP states that land subsidence in the Subbasin has been documented since the 1930s but provides limited information on the current extent and rate of subsidence. The GSP provides historical data from 1939 to 1992 measured at two USGS monitoring sites[90] which indicate that 1.6 feet of subsidence occurred from 1939 to 1960 and between 1960 and

[85] Oxnard Subbasin GSP, Figure 2-28 - 2-32, p. 277-289.

[89] Oxnard Subbasin GSP, Section 2.3.4.7, p. 156.
[90] Oxnard Subbasin GSP, Section 2.3.5, p. 157.

1978 subsidence ranged from 0.3 to 1 foot. The most recent subsidence data provided in the GSP is from a study by Farr et al. (2017) that analyzed interferometric synthetic aperture radar (InSAR) data.[91] The study showed that up to one inch of subsidence occurred throughout the Subbasin between May 2015 and August 2016 and up to two inches of subsidence occurred in isolated areas.[92] Department staff find the GSP's discussion of the rate of historical subsidence, based on observed data, to be reasonable.

Using information from a 2003 USGS modeling study, the GSP predicts that areas within the Oxnard Plain may experience an additional 0.1 to 1 feet of subsidence by 2040, depending on whether future water levels decline below previous low levels and remain there for a considerable amount of time. Based on this assumption, the Agency plans to limit future subsidence by maintaining water levels above historical low levels.[93]

The GSP states that all surface water bodies in the Subbasin may have a connection to the semi-perched aquifer. These surface water bodies include the Santa Clara River, Calleguas Creek, Revolon Slough, Mugu Lagoon, Ormond Beach, and McGrath Lake. The GSP states that the connection between these surface water bodies and underlying groundwater is not fully understood due to limited groundwater elevation data for the semi-perched aquifer and the absence of monitoring sites near surface water bodies.[94] Nevertheless, as described in the hydrogeological conceptual model, a previous investigation found that water can migrate vertically between the Semi-perched Aquifer and the underlying Oxnard Aquifer.[95] Furthermore, Appendix C of the GSP includes a numerical modelling study which provides an estimate of groundwater-surface water connections for a few surface water systems. The numerical model simulates leakage from major surface water bodies using data from stream gauges and estimated aquifer properties. The model shows that the Santa Clara River exhibited recharge to the semi-perched aquifer for 19 out of 31 years [96] and recharged the Upper Aquifer System for 27 out of 31 years [97]; Calleguas Creek exhibited recharge to the semi-perched aquifer in all modeled years. Determining the location of interconnected surface water with groundwater, including the semi-perched aquifer with the Upper Aquifer System, will be necessary to understand and manage the depletion of interconnected surface water in the Subbasin. (see Recommended Corrective Action 1).[98]

The GSP identifies six surface water bodies within the Subbasin as GDEs and potential GDEs. The GDEs include the Lower Santa Clara River, McGrath Lake, Ormond Beach, and Mugu Lagoon, whereas the potential GDEs include Revolon Slough and Lower

Calleguas Creek. Revolon Slough and Lower Calleguas Creek are identified as potential GDEs due to a lack of groundwater level data to confirm whether riparian vegetation are supported by groundwater.[99] The location and the extent of GDEs are shown in maps based on data made available by the Department and other sources.[100] The GSP provides detailed descriptions of the types of ecosystems, the habitat supported by the ecosystems, and the connection of the ecosystem to the underlying semi-perched aquifer. The GSP states that additional data need to be collected within the boundaries of two potential GDEs to understand their connection to the underlying aquifer.

4.2.4 Water Budgets

The GSP used the Ventura Regional Groundwater Flow Model to develop the water budgets for the Subbasin. The Regional Groundwater Flow Model is based on USGS's numerical groundwater flow model (MODFLOW) and was created by UWCD for the Oxnard Subbasin, Mound Basin, the western part of the Las Posas Valley Basin, and Pleasant Valley Basin.[101] The GSP states that the UWCD model was revised, peer reviewed, and finalized in June 2018 for the Oxnard Subbasin GSP[102] and was used to estimate historical, current, and projected water budgets and the sustainable yield.

The GSP provides detailed descriptions of the sources of inflows, outflows, and the use of imported water and recycled water in the Subbasin. The GSP defines the period of 1985 to 2015 as the historical water budget, with the year 2015 as the current water budget.[103] The GSP includes a historical water budget for the semi-perched aquifer, the Upper Aquifer System, and the Lower Aquifer System. It also provides estimates of annual inflows, outflows, and change in storage.[104] Additional data pertaining to the water budget components, such as summary of water deliveries, detailed accounting of recharge by source type, and groundwater use by beneficial uses for each aquifer system are provided in the GSP as required by the GSP Regulations.

The GSP quantified overdraft in the Subbasin using the water year during which water supply conditions approximated average conditions. This calculation method excluded wet, dry, and critically dry water years. The GSP estimates that the overdraft in the Subbasin was about 2,300 acre-feet per year. Based on historical water supply conditions, the GSP evaluates the availability and reliability of water supply deliveries and states that most of the surface water supply sources are reliable and are not significantly affected by the water year type, other than the diversions from the Santa Clara River, which vary widely depending on climate conditions.

The GSP discusses the current water budget for calendar year 2015 and states that the Subbasin had greater outflows than inflows, resulting in a storage loss of 38,703 acre-

[99] Oxnard Subbasin GSP, Section 2.3.7, p. 159-162, Figure 2-52, p. 339.
[100] Oxnard Subbasin GSP, Figure 2-52 - 2-56, p. 339-347.
[101] Oxnard Subbasin GSP, Appendix C, p. 918-1271.
[102] Oxnard Subbasin GSP, Appendix E, p. 1664-1740.
[103] Oxnard Subbasin GSP, Section 2.4.3.2, p. 173-174.
[104] Oxnard Subbasin GSP, Table 2-7a - 2-7c, p. 207-210.

feet.[105] This change in groundwater storage includes seawater intrusion, meaning the groundwater storage decline would have been larger if seawater had not infiltrated the aquifers in the Subbasin. The GSP states that the net seawater intrusion in 2015 was approximately 19,200 acre-feet and affected the Upper Aquifer System and the Lower Aquifer System, whereas the semi-perched aquifer experienced net outflow of water to the Pacific Ocean and was not affected by seawater intrusion.

The Agency developed eight model scenarios to assess the projected water budget and future sustainable yield.[106] The scenarios incorporated existing projects, variable amounts of reduced groundwater production, various climate and precipitation projections, both the 2030 and 2070 climate-change factors, and covered a 50-year time frame, from 2020 to 2069. The GSP states that none of the modeled scenarios successfully eliminated seawater intrusion[107] and, therefore, none of the direct model scenarios were used to determine the sustainable yield of the Oxnard Subbasin. Instead, the findings from six model scenarios were plotted graphically and a statistical method of linear regression was used to calculate the future sustainable yield that would result in zero seawater intrusion.[108] This groundwater production volume with no seawater intrusion is provided in the GSP as the future sustainable yield. The future sustainable yield of the Upper Aquifer System is estimated to be 32,000 acre-feet per year, and the Lower Aquifer System is estimated to be 7,000 acre-feet per year.[109] Therefore, the combined future sustainable yield of Upper Aquifer System and Lower Aquifer System would be 39,000 acre-feet per year, which is equal to the modeled historical sustainable yield of the Subbasin.[110] The future sustainable yield, which is equivalent to the future groundwater production rate of 39,000 acre-feet per year, is substantially lower than the groundwater production in 2015, which was 80,814 acre-feet.[111]

Department staff note that the approach the Agency used to estimate sustainable yield was the subject of several comments. The comments in general questioned the statistical method used and how modeling outputs were utilized. Department staff reviewed the approach and determined that, while novel, the approach to estimate sustainable yield appears to be reasonable. The model relied on is peer-reviewed and is reasonably well-calibrated, and the statistical method utilized is consistent with scientific standards of practice. While other methods could have been employed to estimate sustainable yield, Department staff do not believe that, at this time, the Agency erred in its approach.

Overall, Department staff believe the rationale and information utilized to develop the water budgets is sufficiently thorough and substantially complies with the GSP Regulations. The components of the water budgets, the accounting of the inflows and

outflows to the Subbasin, and availability of water supply for the future are sufficiently detailed and substantially comply with the GSP Regulations. The estimated overdraft, sustainable yield, and change in storage appear to be reasonable and based on the best available information and science. The GSP adequately discusses uncertainties in the water budget and the impact of population growth and future land use on the projected water budget.

4.2.5 Management Areas

The Agency divided the Oxnard Subbasin into five management areas. It appears to Staff that these management areas were created primarily for purposes of implementing the GSP's proposed projects and management actions. The Subbasin is divided into the Forebay, West Oxnard Plain, Oxnard Pumping Depression, Saline Intrusion, and East Oxnard Plain Management Areas.[112] The GSP states that these areas are separated by hydrogeologic properties, groundwater quality, or historical groundwater elevations (see Table 1). Based on information in the Plan, Staff believe that the Agency does not intend to use these management areas to establish differing minimum thresholds or measurable objectives.

Table 1: Summary of Oxnard Subbasin management areas as described in the Oxnard Subbasin GSP

Name	Description
Forebay Management Area	An unconfined part of the Subbasin and a key recharge area where most of the spreading grounds are located.
West Oxnard Plain Management Area	Jurisdictional area that includes the FCGMA and the City of Oxnard.
Oxnard Pumping Depression Management Area	Established based on the low groundwater elevations historically recorded in both the Upper Aquifer System and the Lower Aquifer System in the area.
Saline Intrusion Management Area	Part of the Subbasin where saline intrusion has historically occurred and has impacted wells in both the Upper Aquifer System and Lower Aquifer System.
East Oxnard Plain Management Area	Established based on differences in groundwater elevation and chloride concentration across the Bailey Fault, which acts as a barrier to groundwater flow.

4.3 SUSTAINABLE MANAGEMENT CRITERIA

GSP Regulations require each Plan to include a sustainability goal for the basin and to characterize and establish undesirable results, minimum thresholds, and measurable objectives for each applicable sustainability indicator, as appropriate.[113]

4.3.1 Evaluation Summary

Department staff find the sustainable management criteria included in the GSP were developed using sufficient and credible information and science, and substantially comply

[112] Oxnard Subbasin GSP, Section 2.5, p. 191-192.
[113] 23 CCR § 354.22 *et seq*.

in form and presentation with the requirements outlined in the GSP Regulations. Significant and unreasonable conditions, as defined in the GSP, are based on historical conditions in the Subbasin and their avoidance represents a reasonable approach to achieving the sustainability goal for the Subbasin. The GSP establishes minimum thresholds and measurable objectives that, over time, aim to substantially maintain or improve groundwater conditions in comparison to those present in 2015. Groundwater elevations that achieve the sustainability goal for seawater intrusion were, in turn, used as a proxy for other sustainability indicators. Department staff find this approach is reasonably likely to limit further seawater intrusion and degradation of groundwater quality, avoid land subsidence that substantially interferes with surface land uses, and not worsen impacts to interconnected surface water from current conditions.

While Department staff find, at this time, that the GSP's approach and rationale for establishing sustainable management criteria to be reasonable, further work will be necessary to support the approach and appropriately define the scope of the GSP's evaluation of water quality, subsidence and depletions of interconnected surface water, and potential undesirable results. Department staff strongly encourage the GSAs to address any recommended corrective actions no later than the first five-year update.

4.3.2 Sustainability Goal

The sustainability goal for the Subbasin is to increase groundwater elevations inland of the Pacific coast in order to prevent landward migration of the 2015 saline water impact front and to prevent net seawater intrusion in the Upper Aquifer System and the Lower Aquifer System.[114] The GSP includes multiple projects and management actions that, if implemented, will allow the Subbasin to operate within its sustainable yield and achieve its sustainability goal. The primary management action that will be implemented to achieve the sustainability goal is reducing groundwater production from both the Upper Aquifer System and the Lower Aquifer System,[115] which is anticipated to begin during the first five years following GSP adoption.[116] Department staff find that the GSP sets reasonable sustainability goals and adequately describes the measures to be implemented to achieve sustainable management of groundwater within 20 years and substantially complies with the GSP Regulations.

4.3.3 Sustainability Indicators

GSP Regulations specify that an agency define conditions that constitute sustainable groundwater management for a basin, including the characterization of undesirable results and the establishment of minimum thresholds and measurable objectives for each applicable sustainability indicator.[117]

Sustainability indicators are defined as any of the effects caused by groundwater conditions occurring throughout the basin that, when significant and unreasonable, cause

[114] Oxnard Subbasin GSP, Section 3.2, p. 408.
[115] Oxnard Subbasin GSP, Section 5.1, p. 536.
[116] Oxnard Subbasin GSP, Section 3.2, p. 408.
[117] 23 CCR § 354.22 *et seq*.

undesirable results.[118] Sustainability indicators thus correspond with the six undesirable results – chronic lowering of groundwater levels indicating a significant and unreasonable depletion of supply if continued over the planning and implementation horizon, significant and unreasonable reduction of groundwater storage, significant and unreasonable seawater intrusion, significant and unreasonable degraded water quality, including the migration of contaminant plumes that impair water supplies, land subsidence that substantially interferes with surface land uses, and depletions of interconnected surface water that have significant and unreasonable adverse impacts on beneficial uses of the surface water[119] – but refer to groundwater conditions that are not, in and of themselves, significant and unreasonable. Rather, sustainability indicators refer to the effects caused by changing groundwater conditions that are monitored, and for which criteria in the form of minimum thresholds are established by the agency to define when the effect becomes significant and unreasonable, producing an undesirable result.

The following subsections thus consolidate three facets of sustainable management criteria: undesirable results, minimum thresholds, and measurable objectives. Information, as presented in the GSP, pertaining to the processes and criteria relied upon to define undesirable results applicable to the basin, as quantified through the establishment of minimum thresholds, are addressed for each sustainability indicator. However, a submitting agency is not required to establish criteria for undesirable results that the agency can demonstrate are not present and are not likely to occur in a basin.[120]

4.3.3.1 Chronic Lowering of Groundwater Levels

The GSP states that the chronic lowering of groundwater levels resulting in a significant and unreasonable depletion of supply is an undesirable result applicable to the Oxnard Subbasin and acknowledges that groundwater production in excess of natural and artificial recharge is the primary cause of the chronic lowering of groundwater levels.[121] Significant and unreasonable lowering of levels may result in net seawater intrusion in the Upper Aquifer System and Lower Aquifer System over climate cycles of drought and recovery.[122] The GSP explains the criterion used to define when and where undesirable results occur is landward migration of the 2015 saline water impact front during the period from 2040 through 2069; and the quantitative criteria is:[123]

1. A number of key wells with water levels below their respective minimum thresholds. The Agency selected fifteen key wells in the Upper Aquifer System and nineteen key wells in the Lower Aquifer System for monitoring and to define undesirable results. In the Upper Aquifer System, undesirable results will occur if water levels in six of the 15 key wells are below their respective minimum thresholds in any single monitoring event. Similarly, the Lower Aquifer System will

[122] Oxnard Subbasin GSP, Section 3.3.1 p. 409.
[123] Oxnard Subbasin GSP, Section 3.3.7, p. 417-419.

experience undesirable results if water levels in eight of the 19 key wells are below their respective minimum thresholds in any single monitoring event.

2. Water levels going below the historical low at the respective key monitoring wells. Under this definition, an undesirable result would occur if the groundwater elevation at any individual key well is below the historical low water level for that well.

3. A period of time during which groundwater level exceeds the minimum threshold in any key well. Under this definition, an undesirable result would occur if the water level in any key well was below the respective minimum threshold for either three consecutive monitoring events or three of five consecutive monitoring events.

The Agency established minimum thresholds for groundwater levels based on historical groundwater elevation data and future groundwater model scenarios with potential for seawater intrusion. Specifically, the selected minimum thresholds were based on the lowest simulated groundwater elevation between 2040 and 2069, in which net seawater intrusion was minimal. To account for some of the uncertainty in the projected groundwater elevations, the lowest simulated value was rounded down to the nearest 5-foot interval and then raised by two feet to account for predicted sea level rise by 2070. The GSP states that the established minimum thresholds are water levels that would limit net seawater intrusion into the Upper Aquifer System and Lower Aquifer System, limit migration of the 2015 saline water impact front after 2040[124], and indicate that declines in levels during periods of drought will be offset by increases in levels during periods of above-average rainfall. [125] According to the second criterion above, groundwater elevations are higher than previous historical low water levels.

The GSP establishes measurable objectives for each key well as water levels at which there is neither seawater flow into nor freshwater flow out of the Upper Aquifer System or Lower Aquifer System.[126] According to the GSP, there is at least 10 feet between the measurable objective and the minimum threshold water level, which the Agency considers a margin of safety for operational flexibility.

The GSP describes two sets of interim milestones that represent two paths to achieve the sustainability goal for the Subbasin within 20 years of implementation. With the first path, water levels will reach the measurable objectives under average climatic conditions, and with the second path, water levels will reach minimum thresholds under dry conditions.[127] The GSP states that the interim milestones should be reassessed during future GSP updates in conjunction with measured groundwater levels at each key well.[128]

[124] Department staff's understanding of "after 2040" is January 1st, 2041. See Oxnard Subbasin GSP, p. 28 footnote 2 and definition of sustainability goal on p. 408.
[125] Oxnard Subbasin GSP, Section 3.3.1, p. 410, Section 3.4.1, p. 420.
[126] Oxnard Subbasin GSP, Section 3.5.1, p. 427.
[127] Oxnard Subbasin GSP, Table 3-2, p. 437-438, Figure 3-12, p. 469.
[128] Oxnard Subbasin GSP, Section 3.5.1, p. 429.

The GSP states that the minimum thresholds are anticipated to improve conditions for beneficial uses of the Subbasin by limiting seawater intrusion and chronic lowering of groundwater levels.[129] While it seems reasonable to anticipate improvements at the minimum thresholds, the GSP does not provide specific information on how the minimum thresholds may affect the interests of beneficial uses and users of groundwater in the Subbasin. In particular, the Department understands that there are domestic wells in the Subbasin, and the Plan does not provide an assessment of how the minimum thresholds affect domestic wells. Department staff encourage the Plan provide more specific information detailing potential effects of minimum thresholds on beneficial users and uses of groundwater, on land uses, and on property interests in the Subbasin. Nonetheless, established minimum thresholds represent levels above historical lows,[130] which represents an approach that is consistent with SGMA and the GSP Regulations.

Department staff find the sustainable management criteria defined for chronic lowering of groundwater levels is commensurate with the level of understanding of the basin setting and establishes reasonable criteria to achieve the sustainability goal of the Subbasin. Based on the thresholds established by the Agency, the groundwater level will show the first sign of recovery by 2025 when the groundwater level in every key well is anticipated to be above 2015 groundwater levels; groundwater levels will progressively improve until 2040.[131] Establishing sustainable management criteria that aims to prevent advancement of the 2015 saline water impact front is a reasonable approach that will help avoid a significant and unreasonable depletion of groundwater supply in the Subbasin.

4.3.3.2 Reduction of Groundwater Storage

The Plan states that the significant and unreasonable reduction of groundwater storage is an undesirable result that applies to Oxnard Subbasin.[132] The Plan acknowledges that the primary cause of reduction in groundwater storage is groundwater production in excess of recharge. The Plan states that significant and unreasonable reduction of groundwater storage may result if the volume of water produced from the Subbasin exceeds the volume of freshwater recharging the Subbasin over cycles of drought and recovery, and this undesirable result that has already occurred in the Subbasin.[133]

The Plan's definition for an undesirable result associated with "reduction in groundwater storage is landward migration of the 2015 saline water impact front after 2040."[134] The minimum thresholds established are the same water levels that limit seawater intrusion in the Subbasin, and indicate that declines in groundwater elevation during periods of drought will be offset by recovery during periods of above-average rainfall.[135] The

[130] Oxnard Subbasin GSP, Section 3.3.1, p. 410.
[131] Oxnard Subbasin GSP, Table 3-2, p. 437-438.
[132] Oxnard Subbasin GSP, Section 3.3.2, p. 411.
[133] Oxnard Subbasin GSP, Section 3.3.2, p. 411.
[134] Oxnard Subbasin GSP, Section 3.3.2, p. 411.
[135] Oxnard Subbasin GSP, Section 3.4.2, p. 421.

established elevations are higher than previous historical low water levels. The measurable objective for seawater intrusion is defined as the groundwater level at which there is neither seawater flow into, nor freshwater flow out of, the Upper Aquifer System and Lower Aquifer System; the measurable objective for each key well is based on the simulated median groundwater elevation between 2040 and 2070 that minimizes the migration of the 2015 saline water impact front after 2040.[136]

The Plan states that undesirable results related to a reduction of groundwater storage have already occurred in the Subbasin.[137] These undesirable results have the potential to impact the beneficial uses and users of groundwater by limiting the volume of groundwater available for agriculture, municipal, industrial, domestic, and environmental uses.

Department staff find the sustainable management criteria defined for reduction of groundwater in storage, in particular connecting the reduction in storage to seawater intrusion, is commensurate with the level of understanding of the basin setting and establishes reasonable criteria for this particular sustainability indicator. Preventing a reduction in groundwater storage in the Subbasin from getting worse than those conditions experienced in 2015 is a reasonable approach that will help avoid a significant and unreasonable depletion of supply in the Subbasin. The Plan states that selected management criteria are anticipated to improve the beneficial uses of the Subbasin by allowing for long-term use of groundwater supplies in the Subbasin without replacing freshwater in the Upper Aquifer System and Lower Aquifer System with seawater. The anticipated improvement appears to be reasonable. However, under the dry condition scenario (i.e., projected water levels at the minimum thresholds) landward migration of seawater, while minimized, is still expected until 2040. If this is the case, analysis should be provided to describe how continued seawater intrusion may affect the interests of beneficial uses and users of groundwater in the Subbasin (see Recommended Corrective Action 2).

4.3.3.3 Seawater Intrusion

The Plan defines significant and unreasonable seawater intrusion as a net landward migration of the 2015 saline water impact front beyond the already-impacted area from 2040 through 2069.[138] This saline water impact area is characterized by concentrations of chloride greater than 500 milligrams per liter, is generally located west of Highway 1 and south of Hueneme Road, and is sourced by modern seawater as well as non-marine brines and connate water in fine-grained sediments.[139] The Agency plans to limit

[136] Oxnard Subbasin GSP, Section 1.1, Footnote 2, p. 28, Section 3.5.2, p. 429.
[137] Oxnard Subbasin GSP, Section 3.3.2, p. 411.
[138] Oxnard Subbasin GSP, Section 3.3.3, p. 412.
[139] Oxnard Subbasin GSP, Section 3.3.3, p. 412.

seawater intrusion to the area that has already been impacted but does not intend to reverse or improve the historically impacted area.[140]

According to the GSP, modeling by UCWD indicates a strong relationship between groundwater elevation and seawater intrusion and, therefore, the minimum thresholds for seawater intrusion are based on groundwater levels that limit seawater intrusion in the Upper Aquifer System and Lower Aquifer System.[141] The measurable objective for seawater intrusion is defined as the groundwater level at which there is neither seawater flow into nor freshwater flow out of the Upper Aquifer System and Lower Aquifer System; the measurable objective for each key well is based on the simulated median groundwater elevation between 2040 and 2070 that minimizes the migration of the 2015 saline water impact front after 2040.[142] The GSP states that model simulations suggest that if groundwater levels fall below the minimum threshold elevations, the Subbasin is likely to experience net landward migration of seawater intrusion after 2040.[143] The minimum thresholds are anticipated to improve the beneficial uses of the Subbasin by limiting seawater intrusion.[144]

Department staff conclude that the sustainable management criteria defined in the GSP for seawater intrusion are commensurate with the understanding of seawater intrusion in the Subbasin and will be reasonably protective of the beneficial uses and users of groundwater in the Subbasin, and if progress toward the minimum threshold or measurable objective is achieved, will have a positive impact on groundwater users. Furthermore, preventing further long-term seawater intrusion will be beneficial to users in the Subbasin who may reside in areas at risk from further intrusion.

However, Department staff understands that until groundwater levels are at the minimum thresholds there is a potential for further seawater intrusion. Under the dry conditions scenario presented in the Plan, reaching the minimum thresholds may not happen until 2040. Department staff thus recommend the Agency provide additional information on the potential impacts of seawater intrusion on the beneficial uses and users, including domestic users, that are inland of the 2015 saline water impact area if landward migration of the front continues (see Recommended Corrective Action 2).

4.3.3.4 Degraded Water Quality

The GSP states that significant and unreasonable degraded water quality related to groundwater production is an undesirable result that has the potential to occur in the Subbasin and that the main constituents of concern for SGMA purposes are TDS and chloride.[145] Significant and unreasonable degradation of water quality may occur if there

[140] Oxnard Subbasin GSP, Section 3.3.3, p. 412.
[141] Oxnard Subbasin GSP, Section 3.4.3, p. 422.
[142] Oxnard Subbasin GSP, Section 1.1, Footnote 2, p. 28, Section 3.5.3 p. 430.
[143] Oxnard Subbasin GSP, Section 3.4.3, p. 422.
[144] Oxnard Subbasin GSP, Section 3.4.3, p. 422.
[145] Oxnard Subbasin GSP, Section 3.3.4.1, p. 414.

is an expansion of the areas currently impacted by elevated concentrations of chloride and TDS that limit agricultural and potable use of groundwater.

The GSP states that the sustainable management criteria for chronic lowering of groundwater levels are used as a proxy for water quality, rather than concentrations of chloride and TDS, because the elevated concentrations of chloride and TDS are associated with groundwater production resulting in seawater intrusion and release of connate brines into aquifers. The GSP explains minimum thresholds established are water levels that prevent net migration of the 2015 saline water impact front after 2040.[146] The measurable objective is defined as the groundwater level at which there is neither seawater flow into nor freshwater flow out of the Upper Aquifer System and Lower Aquifer System; the measurable objective for each key well is based on the simulated median groundwater elevation between 2040 and 2070 that minimizes the migration of the 2015 saline water impact front after 2040.[147]

Department staff conclude that the GSP's approach of using groundwater levels as a proxy for its water quality sustainable management criteria for chloride and TDS specifically, is generally reasonable and consistent with the GSP Regulations. However, as recognized in the GSP, the effectiveness of applying a water level proxy to groundwater quality degradation needs to be assessed through continued monitoring.[148] It is not established at this time how groundwater levels will ensure that groundwater use subject to the GSAs jurisdiction does not significantly and unreasonably exacerbate existing degraded water quality conditions. While the Department is unaware of information demonstrating that groundwater production is impacting water quality in the Subbasin, Department staff recommend the GSAs assess water quality monitoring data and coordinate with the appropriate water quality regulatory programs and agencies to better understand how the established groundwater level thresholds are protective of groundwater quality, and not just limited to saline water, and to provide supporting data and information to ensure that groundwater quality is not exacerbated by groundwater use in the Subbasin (see Recommended Corrective Action 4).

In addition, the GSP identifies groundwater from the semi-perched aquifer as one of the primary reasons for degraded water quality[149] and acknowledges that water can migrate vertically from the semi-perched aquifer to the underlying Oxnard aquifer.[150] The GSP lacks adequate assessment and characterization of the potential for migration of degraded water to impair water supplies that may lead to undesirable results.[151] Therefore, Department staff recommend the Agency investigate the potential for

[146] Oxnard Subbasin GSP, Section 3.4.4, p. 424.

[151] 23 CCR § 354.28(c)(4).

groundwater pumping to result in migration of impaired water (see Recommended Corrective Action 1).

Lastly, the Plan acknowledges that elevated nitrate concentrations in the Forebay area have resulted in significant and unreasonable impacts to beneficial uses and users of the Subbasin.[152] Notably, nitrate concentrations in UWCD shallow supply wells tend to increase during periods of drought.[153] Nitrate concentrations above water quality objectives and basin management objectives are routinely detected in the Subbasin and likely caused by historical septic discharges and agricultural fertilizer application practices.[154] However, the GSP states that nitrate concentrations are not negatively impacted by their groundwater production, not anticipated to expand geographically, and, therefore, are not considered a SGMA sustainability indicator.[155] No minimum threshold is established for nitrate because the Agency believes nitrate concentrations are not negatively impacted by their groundwater production; will be diluted by maintaining and potentially increasing surface-water recharge from the Santa Clara River; and will decline in the long term due to modern agronomic fertilization practices and cessation of septic discharges. The GSP states that groundwater levels will be used as a proxy to prevent further degradation of groundwater quality in the Forebay area until a separate minimum threshold concentration for nitrate is found to be necessary.[156] At this time, Department staff find the GSP's approach to nitrate to be reasonable and encourage the GSAs to continue monitoring and assessing the relationship between groundwater production and nitrate concentrations.

4.3.3.5 Land Subsidence

The GSP defines the undesirable result associated with land subsidence as subsidence that substantially interferes with surface land uses.[157] Although the GSP does not explicitly describe whether land subsidence has impacted beneficial uses and users, the Agency recognizes the potential for land subsidence to impact infrastructure and states that subsidence associated with groundwater production has not caused and is not likely to cause undesirable results.[158] Furthermore, the GSP states that the projected 0.1 to 1 feet of subsidence that is anticipated to occur by 2040 will not substantially interfere with surface land uses in the Subbasin.

The GSP discusses historical land subsidence studies and subsidence rates, then hypothesizes that maintaining groundwater levels above historical lows will avoid subsidence related to groundwater production. Thus, the Agency intends to use groundwater levels as a proxy to monitor and avoid undesirable results related to subsidence. Although Department staff find the approach to be reasonable, staff also

[157] Oxnard Subbasin GSP, Section 3.3.5, p. 415.
[158] Oxnard Subbasin GSP, Section 3.3.5, p. 416.

recommend the Agency incorporate periodic monitoring (e.g., for each five-year update) for land subsidence that can provide the Agency with quantitative data regarding the performance of the proxy (see Recommended Corrective Action 3).

4.3.3.6 Depletions of Interconnected Surface Water

The Plan defines the undesirable result associated with depletion of interconnected surface water in the Oxnard Subbasin as a loss of GDE habitat. The Plan recognizes four GDEs and two potential GDEs and states that the health of GDEs depends on conditions of the semi-perched aquifer. Based on the stable groundwater elevation and low rate of groundwater production from the semi-perched aquifer, the Plan states that the loss of GDEs is not occurring and has not occurred in the past; thus, the Subbasin is not experiencing undesirable results for this sustainability indicator.[159] The Plan acknowledges data gaps regarding the confirmation of the potential GDEs and their hydraulic connection with the semi-perched aquifer.

The Plan explains that the minimum thresholds for depletion of interconnected surface water are water levels that limit seawater intrusion in the Subbasin and indicate that declines in groundwater elevations during periods of future drought will be offset by recoveries during future periods of above-average rainfall.[160] The Plan states that minimum thresholds are not established for the semi-perched aquifer because this unit is not considered a principal aquifer. Instead, the Plan explains that the simulated minimum thresholds established for the underlying Oxnard aquifer, which would prevent landward migration of the 2015 saline water impact front, were also found to result in higher water levels in the semi-perched aquifer.[161] The Plan states that historical groundwater levels in the semi-perched aquifer have supported GDEs and that the minimum thresholds for the Oxnard aquifer would result in higher groundwater elevations in the semi-perched aquifer, which would be protective of GDEs.[162]

Determining the connection between the surface water bodies and the underlying aquifers, including the semi-perched aquifer and the principal aquifers, will be necessary to understand and manage the depletion of interconnected surface water in the Subbasin. Department staff recommend the GSAs improve their understanding of interconnected surface water systems and the potential GDEs that may rely on those systems (see Recommended Corrective Action 1).

Department staff believe that if the proxy of using the minimum threshold established for groundwater levels for the Oxnard aquifer results in higher groundwater elevations in the semi-perched aquifer, this approach is reasonable to avoid the loss of GDEs, given that historical groundwater levels have supported GDEs prior to GSP implementation. However, Department staff believe that there is uncertainty regarding the future

[159] Oxnard Subbasin GSP, Section 3.3.6, p. 416-417.
[160] Oxnard Subbasin GSP, Section 3.4.6, p. 425.
[161] Oxnard Subbasin GSP, Section 3.4.6, p. 425.
[162] Oxnard Subbasin GSP, Section 3.4.6, p. 425.

groundwater condition in the semi-perched aquifer. Because the groundwater level in the semi-perched aquifer has been maintained largely by agricultural return flow,[163] the intended groundwater pumping reduction and agricultural land fallowing[164] could potentially reduce agricultural return flow and affect the future groundwater level conditions in the semi-perched aquifer. Therefore, Department staff believe that the Agency should have a robust monitoring network capable of evaluating whether the use of groundwater levels in the underlying Oxnard aquifer as a proxy for depletion of interconnected surface water is performing as intended and avoiding undesirable results associated with GDEs and the depletion of interconnected surface waters (see Recommended Corrective Action 1).

4.4 MONITORING NETWORKS

GSP Regulations require that a monitoring network be developed for each basin including monitoring objectives, monitoring protocols, and data reporting requirements. The network shall promote the collection of data of sufficient quality, frequency, and distribution to characterize groundwater and related surface water conditions in the basin and evaluate changing conditions.[165]

4.4.1 Evaluation Summary

The monitoring network for the Subbasin was developed to track and monitor parameters that demonstrate progress toward meeting the sustainability goals. In addition to existing groundwater level monitoring programs, the Agency developed a monitoring network which monitors groundwater levels in the Subbasin. Although there are no monitoring networks newly developed for the other five sustainability indicators, the Agency plans to use groundwater level data as a proxy to assess groundwater conditions related to other sustainability indicators.

Although the GSP's monitoring network substantially complies with GSP regulations, the Plan identifies data gaps in each aquifer and in a management area. Department staff concur that there are critical data gaps that should be addressed early in GSP implementation. Failure to do so may make it difficult to demonstrate that implementation of the Plan is achieving the sustainability goal of the Subbasin, which may influence subsequent plan assessments by the Department.

4.4.2 Monitoring Networks

The Agency maintains long-term groundwater and surface water data for groundwater management purposes and to understand Subbasin conditions and responses to climate and land use. Groundwater elevation and surface flow monitoring started in the 1930s, with groundwater extraction data being collected since 1983. Precipitation data has been recorded for more than a century in the Subbasin.

[163] Oxnard Subbasin GSP, Section 2.2.3, p. 123, Section 2.4.1.9, p. 170, Section 2.4.2.2, p. 171,
[164] Oxnard Subbasin GSP, Section 5.6 – Section 5.7, p. 546-551
[165] 23 CCR § 354.32 *et seq*.

The existing groundwater level monitoring network consists of 150 wells that are measured monthly to quarterly; 34 of those wells are selected for representative monitoring. Groundwater level data is being collected by the Ventura County Watershed Protection District and UWCD, which are partner agencies. Because these agencies follow different data collection protocols, the Agency plans to work with these agencies to ensure that future data collection is conducted according to protocol that is consistent with best management practices.[166] The Agency plans to collect groundwater elevation data from the 34 representative wells within a 2-week window in the spring and fall of each year. In addition to manual measurements, the Agency plans to monitor short-term and long-term trends in groundwater elevation using transducers.

The GSP states that the groundwater level monitoring network is structured to provide groundwater elevation data for each primary aquifer and the lateral and vertical gradient within and between the aquifers. The numerical model will be used to calculate the annual change in storage using the collected groundwater level data and will be reported for each aquifer in annual reports.

The Agency has worked with Department's Technical Support Services program to close data gaps by constructing six new monitoring wells in the Oxnard Subbasin. The Agency's rationale for monitoring site selection appears to include wells from all major aquifers and management areas to have temporal and spatial coverage, and the Agency believes that the monitoring network is robust enough to detect Subbasin-wide undesirable results in a timely manner. Because there are no representative monitoring wells located in the East Oxnard Plain Management Area (EOPMA),the Agency intends to use the wells located in the adjacent Oxnard Pumping Depression Management Area to monitor the groundwater conditions in the EOPMA until a monitoring well is installed in the EOPMA.[167] The Agency assumes that the measurable objectives set for the wells located in the Oxnard Pumping Depression Management Area will also protect the EOPMA because of the proximity of the monitoring wells to the EOPMA. Department staff believe that Agency's approach of using key wells located in the adjacent management area for EOPMA is scientifically reasonable and Agency's plan to add a monitoring well in future for an accurate understanding of EOPMA groundwater condition is pragmatic.

The GSP includes over 900 groundwater quality hydrographs which show historical and current water quality data. Some of these hydrographs include water quality data going back to the 1930s. The hydrographs compare the five water quality constituents with Basin Plan Water Quality Objectives or Maximum Contaminant Levels (MCL).[168] The GSP does not include a summary of the historical water quality conditions apart from information provided in hydrographs, but discusses 2011 to 2015 groundwater quality conditions related to the five constituents of concern. The water quality constituents that are currently being monitored in the Subbasin are TDS, chloride, nitrate, sulfate, and

[166] Oxnard Subbasin GSP, Section 4.5, p. 484.
[167] Oxnard Subbasin GSP, Section 3.3.1, p. 410-411.
[168] Oxnard Subbasin GSP, Appendix G, p. 1803-2718.

boron. These water quality constituents are associated with the water quality thresholds either adopted by the Agency or mandated by the LARWQCB. The groundwater quality sampling frequency ranges from quarterly to annually, with data being analyzed to document trends of the constituents identified by FCGMA and the LARWQCB. The Agency chooses not to use the water quality monitoring data for the degraded water quality sustainability indicator; instead, the Agency uses groundwater elevation data as the proxy. The Plan states that the groundwater quality data will continue to be collected and analyzed to assess whether groundwater elevation thresholds are sufficiently protective of groundwater conditions in the Subbasin.[169]

Although the existing water quality monitoring program in the Oxnard Subbasin includes the monitoring of chloride concentration, the Agency chose not to use chloride concentration data to monitor seawater intrusion. Instead, the Agency plans to use groundwater elevation data to monitor and assess seawater intrusion in the Subbasin. The Plan states that their network of 16 dedicated monitoring wells located adjacent to the coast is capable of documenting groundwater elevations that could induce seawater intrusion. The Agency plans to monitor the water quality trends related to seawater intrusion by monitoring each coastal well on an annual basis.

The Agency does not have a monitoring program to directly monitor land subsidence in the Subbasin, stating that it does not anticipate subsidence related to groundwater production to occur because the minimum threshold for groundwater elevations are higher than the historical low groundwater elevations in the Subbasin. The Agency plans to use groundwater elevation data as a proxy for monitoring land subsidence in the Subbasin and states that pre-existing GPS-based benchmarks could be used to monitor land subsidence if the water level falls below historical low levels for an extended period and the potential for land subsidence to substantially interfere with surface land uses is determined.[170] As stated above, Department staff recommend the Agency incorporate periodic monitoring for subsidence, directly, to verify that its assumptions about the proxy are correct (see Recommended Corrective Action 3)

The GSP states that groundwater elevations are monitored in the semi-perched aquifer to document interactions between the semi-perched aquifer and the surface water bodies in the Subbasin, as well as to document potential gradients between the semi-perched aquifer and the underlying Oxnard aquifer.[171] However, the Agency's monitoring network does not include any representative key wells for the semi-perched aquifer; thus, sustainable management criteria are not established for any wells screened solely in the semi-perched aquifer. Although the GSP states that the semi-perched aquifer is not a primary aquifer and is not a significant contributor to groundwater production, the GSP recognizes that impaired groundwater from the semi-perched aquifer[172] could migrate

[169] Oxnard Subbasin GSP, Section 3.3.4.1 - 3.3.4.2, p. 414-415.
[170] Oxnard Subbasin GSP, Section 4.6.4, p. 487.
[171] Oxnard Subbasin GSP, Section 4.3.1, p. 478.
[172] Oxnard Subbasin GSP, Section 2.3.4.7, p. 155.

vertically and impact the underlying Oxnard aquifer.[173] Staff recommend that the GSAs provide additional information to demonstrate that the network can effectively characterize conditions in the semi-perched aquifer and in the vicinity of GDEs (see Recommended Corrective Action 1).

4.5 PROJECTS AND MANAGEMENT ACTIONS

GSP Regulations require a description of the projects and management actions the submitting agency has determined will achieve the sustainability goal for the basin, including projects and management actions to respond to changing conditions in the basin.[174]

4.5.1 Evaluation Summary

The Agency has already been managing groundwater in the Subbasin by implementing various management actions to address the undesirable results described in the GSP. In addition to the currently operational Advanced Water Purification Facility project, the GSP proposes projects that, if implemented, will likely allow the Subbasin to be operated within its sustainable yield by decreasing reliance on groundwater within the Subbasin.

Furthermore, Department staff find that the management actions, which focus largely on reducing groundwater production, directly relate to the sustainable management criteria and present a generally feasible approach to achieving the sustainability goal of the Subbasin and are generally consistent with the requirements of the GSP Regulations. However, the GSP lacks specific details regarding the pumping reduction plan, the projects and management actions that will be implemented, expected timelines of projects and management actions, and when the Agency expects to see benefits from implemented projects and management actions. Department staff understand that many of these details will be developed during the next several years. Since meeting the sustainability goal for the Subbasin is largely dependent on implementation of the projects and in particular the management actions, failure to implement these projects and management actions, or material modifications, may affect the Department's conclusions regarding the adequacy of the GSP or its implementation in future evaluations.

4.5.2 Projects

To meet the sustainability goal of the Subbasin, the Plan provides details for five projects:[175]

1. Complete construction of the Advanced Water Purification Facility (AWPF)
    - Provide City of Oxnard with up to 6.25 million gallons per day for reclaimed water uses

[173] Oxnard Subbasin GSP, Section 2.2.3, p. 122-123, Section 2.3.4.7, p. 156.
[174] 23 CCR § 354.44 *et seq*.
[175] Oxnard Subbasin GSP, Section 5.2, p. 536-548.

2. Expand the capacity of the AWPF to provide additional reclaimed water for recharge
3. River Park-Saticoy Groundwater Replenishment and Reuse Project Recycled Water Project
    - Extend three miles of pipeline to convey water from the AWPF Expansion Project to two groundwater recharge facilities operated by UWCD
4. Freeman Expansion Project
    - Construct facilities capable of diverting Santa Clara River water at higher flow rates and with higher sediment loads
5. Temporary agricultural land fallowing project
    - Use replenishment fees collected by the Agency to lease and temporarily fallow agricultural land in specific areas more susceptible to seawater intrusion

All five projects include a description, the relationship to sustainability criteria, expected benefits, metrics for evaluation, and funding sources. The Plan states that Phase 1 of Project 1 (constructing the AWPF) has already been permitted and constructed and began delivering reclaimed water to agricultural operators in 2016. The AWPF is currently producing up to 4,600 acre-feet of reclaimed water per year

The Agency provided timelines for project implementation to be within 10 years,[176] but the GSP explicitly states that inclusion of these projects in the GSP does not mean the Agency is making a commitment to fund or construct these projects; rather, these projects met various feasibility criteria and were analyzed to understand their impacts on groundwater elevation and the sustainable yield of the Subbasin.[177] The GSP further states that these projects were included because they have quantifiable information for evaluation and modelling rather than because of the project feasibility.[178]

The Agency used the numerical model to simulate scenarios with projects to determine the relationship between projects and groundwater elevations in the Subbasin. The model simulations indicate that groundwater elevations were slightly higher with the proposed projects than without projects[179] and show that the proposed projects are reasonable to address the undesirable results related to seawater intrusion occurring in the Subbasin.[180]

The GSP identifies some uncertainties with respect to the successful implementation of the projects. The operational uncertainties described in the GSP are:

[176] Oxnard Subbasin GSP, Section 5.2, p. 538-548.

[178] Oxnard Subbasin GSP, Section 5.1, p. 535.
[179] Oxnard Subbasin GSP, Section 2.4, p. 177-190; Figure 3-6 - 3-11, p. 449-467.
[180] Oxnard Subbasin GSP, Figure 2-63, p. 361, Appendix E, Figure 4 and Figure 5, p. 1711-1712.

- the source of additional secondary effluent for the expansion of the AWPF project
- the availability of high flow in the Santa Clara River for diversion of additional surface water flow
- the availability of the lessors to participate in the temporary agricultural land fallowing project
- the funding sources for the proposed projects have been identified in the Plan as the replenishment fee and grant fund, but the reliability of these funding sources have not been discussed.

Furthermore, a comment letter received by the Department discusses the disagreement between the agencies regarding implementation of projects 1, 2 and 3, and the letter challenged the Agency's authority to implement the projects identified in the GSP. Department staff recommend FCGMA rectifies the differences between the agencies and arrive at an agreement so that the projects can be implemented in the desired schedule.

Despite the uncertainties discussed above, Department staff find that, at this time, the GSP provides a reasonable discussion of how the projects are related to the basin sustainability and provides a general implementation timeline. The projects are developed by the GSAs to help ensure that the Subbasin will be operated within its sustainable yield and are expected to mitigate the overdraft condition. Therefore, Department staff believe that the projects included in the GSP demonstrate a feasible approach to meet the Subbasin's sustainability goals and appears to help in improving groundwater conditions in the Subbasin.

4.5.3 Management Actions

The GSP describes two management actions, which include reducing groundwater production and a water market pilot program. The GSP discusses the relationship between the management actions and sustainability criteria, expected benefits, metrics for evaluation, and funding sources. The GSP states that reducing groundwater production is the primary management action[181] that can be implemented by the Agency and is a critical component of achieving sustainability.[182] The Agency intended to implement these management actions within five years of GSP adoption, upon approval by the FCGMA board.

In regard to the proposed water market pilot program, the program will allow for transfer of extraction allocations, but excludes transfers in the Saline Water Intrusion Management Area and Pumping Depression Management Area if the transfer results in a net increase in the total market allocation for participants. The participants in these management areas may receive a transfer of market allocation only from another participant in the same

[181] Oxnard Subbasin GSP, Executive Summary, p. 25.
[182] Oxnard Subbasin GSP, Section 5.7.2, p. 549.

management area. In placing these parameters on its market allocation transfers, the Agency aims to avoid undesirable impacts related to seawater intrusion.

The GSP provides an overview of how and when the management actions will be implemented, but also identifies that allocations need to be determined and approved by the GSAs. Department staff believe that both the management actions included in the Plan can reasonably mitigate overdraft and, if implemented, appear likely to help the GSAs achieve sustainability in the Subbasin. Department staff's understanding is that the ability of the GSP to achieve the sustainability goal for the Subbasin is largely dependent on successful implementation of a management action to reduce groundwater pumping. As such, the Department will closely monitor the Agency's progress in developing and implementing such a management action.

4.6 Consideration of Adjacent Basins/Subbasins

SGMA requires the Department to "…evaluate whether a groundwater sustainability plan adversely affects the ability of an adjacent basin to implement their groundwater sustainability plan or impedes achievement of sustainability goals in an adjacent basin."[183] Furthermore, the GSP Regulations state that minimum thresholds defined in each GSP should be designed to avoid causing undesirable results in adjacent basins or affecting the ability of adjacent basins to achieve sustainability goals.[184]

The Oxnard Subbasin has four adjacent basins/subbasins: Pleasant Valley, Las Posas, Mound, and Santa Paula. The Oxnard Subbasin is in hydraulic communication, in varying degrees, with all of those adjacent basins and subbasins. FCGMA is the lead GSA and exclusive GSA for developing and implementing the respective groundwater sustainability plans in the Oxnard Subbasin, Pleasant Valley Basin, and Las Posas Basin. FCGMA took a regional approach to determine the combined sustainable yield of all three basins and then determined the sustainable yield for each groundwater basin. The sustainable management criteria for each respective groundwater sustainability plan were established with consideration for the sustainability goals of the adjacent basins and to operate each groundwater basin within their sustainable yield.

The GSP of Mound Subbasin is being developed by the Mound Basin GSA, which is a joint powers authority comprised of three local public agencies. Department staff recommend that the Agency continue to collaborate and communicate with the Mound Basin GSA to ensure that the basins in the region do not prevent each other from achieving sustainability.

The Santa Paula Subbasin is an adjudicated basin currently managed by UWCD per the physical solution embodied within the Court Judgment. Department staff recommend that

[183] Water Code § 10733(c).
[184] 23 CCR § 354.28(b)(3).

the GSAs work with UWCD to corroborate that the implementation of Oxnard GSP does not adversely affect the UWCD's management of the Santa Paula.

Department staff understand that the established sustainability management criteria and strategy to reach sustainability in the Oxnard Subbasin is primarily related to improving groundwater levels in the principal aquifers and avoiding seawater intrusion. Based on this strategy, on the Agency's history of actively collaborating with local agencies, other information provided in the Plan, and because the Agency took a regional approach in developing the respective groundwater sustainability plans and provided reasonable consideration to adjacent basins and their sustainability metrics, Department staff determined that the Oxnard Subbasin GSP will not adversely impact the ability of the adjacent basins to be operated sustainably and will not impede the adjacent basins' ability to achieve their respective sustainability goals.

5 STAFF RECOMMENDATION

Department staff's recommendation is to approve the GSP with the recommended corrective actions listed below. The Oxnard Subbasin GSP conforms with Water Code Sections 10727.2 and 10727.4 of SGMA and substantially complies with the GSP Regulations. Implementation of the GSP will likely achieve the sustainability goal for the Oxnard Subbasin. The GSAs have identified several areas for improvement of the GSP and Department staff concur that those items are important and should be addressed as soon as possible. Department staff have also identified additional recommended corrective actions that should be considered by the GSAs for the first five-year assessment of its GSP. Addressing these recommended corrective actions will be important to demonstrate that implementation of the GSP is likely to achieve the sustainability goal. The recommended corrective actions include:

RECOMMENDED CORRECTIVE ACTION 1

Investigate the hydraulic connectivity between the surface water bodies, semi-perched aquifer, and principal aquifers to improve the understanding of potential migration of impaired water, the reliance of two potential GDEs on the semi-perched aquifer, and depletion of interconnected surface water bodies. Also, identify specific locations of gaining and losing reaches of surface water bodies and quantify the depletion of interconnected surface water. Describe schedule and steps that will be taken to fill data gaps identified in the GSP related to shallow groundwater monitoring near surface water bodies and GDEs.

RECOMMENDED CORRECTIVE ACTION 2

Under the dry climatic condition scenario, the groundwater levels will only reach minimum thresholds by 2040, which will limit seawater intrusion but not necessarily avoid the condition. Discuss the impact of further seawater intrusion and associated loss of storage on beneficial uses and users under the dry climatic condition scenario and the potential impacts to uses and users inland of the 2015 saline water impact area if landward migration of the saline water impact front continues.

RECOMMENDED CORRECTIVE ACTION 3

Incorporate periodic subsidence monitoring into the GSP's monitoring plan that can be used to quantify whether land subsidence is occurring and whether the groundwater level proxy is avoiding undesirable results associated with land subsidence. As an option, the Department provides statewide InSAR data that can be used for monitoring land subsidence.

RECOMMENDED CORRECTIVE ACTION 4

Elaborate how the Agency is planning to verify that the groundwater level thresholds are adequate to assess the groundwater quality conditions in the Subbasin. Discuss how the groundwater quality data from the existing monitoring network will be used for sustainable management of the Subbasin. Coordinate with the appropriate groundwater users, as identified in the GSP, and the appropriate water quality agencies in the Subbasin to evaluate how the Agency's current groundwater management strategy is affecting the groundwater quality in the Subbasin.

Drinking Water Regulations and Contaminants

On this page:

- National primary drinking water regulations (NPDWRs)
- List of drinking water contaminants and their maximum contaminant levels (MCLs)
- National secondary drinking water regulations (NSDWRs)
- List of secondary drinking water regulations
- Unregulated drinking water contaminants

National Primary Drinking Water Regulations (NPDWRs)

NPDWR (National Primary Drinking Water Regulations)s (or primary standards) are legally enforceable standards that apply to public water systems.

Additional Resource

- NPDWR Alphabetical List (PDF)(6 pp, 924 K, About PDF <https://epa.gov/home/pdf-files>) EPA 816-F-09-004, May 2009

Primary standards protect public health by limiting the levels of contaminants in drinking water.

- Regulation Timeline: Contaminants Regulated Under the Safe Drinking Water Act <https://epa.gov/node/119195/>
- Read more information about NPDWRs in the Code of Federal Regulations <https://epa.gov/dwregdev/how-epa-regulates-drinking-water-contaminants-documents>

List of Primary Drinking Water Contaminants and their Maximum Contaminant Levels (MCLs)

- Table of Regulated Drinking Water Contaminants <https://epa.gov/ground-water-and-drinking-water/national-primary-drinking-water-regulations>

National Secondary Drinking Water Regulations (NSDWRs)

NSDWRs (or secondary standards) are non-enforceable guidelines regulating contaminants that may cause cosmetic effects (such as skin or tooth discoloration) or aesthetic effects (such as taste, odor, or color) in drinking water. EPA recommends secondary standards to water systems but does not require systems to comply with the standard. However, states may choose to adopt them as enforceable standards.

While secondary standards are not federally enforceable, EPA requires a special notice for exceedance of the fluoride secondary standard of 2.0 mg/L. Community water systems that exceed the fluoride secondary standard of 2 mg/L, but do not exceed the primary standard of 4.0 mg/L for fluoride, must provide public notice to persons served no later than 12 months from the day the water system learns of the exceedance (40 CFR 141.208).

List of National Secondary Drinking Water Regulations

Contaminant	Secondary Standard
Aluminum	0.05 to 0.2 mg/L
Chloride	250 mg/L
Color	15 (color units)
Copper	1.0 mg/L
Corrosivity	noncorrosive
Fluoride	2.0 mg/L
Foaming Agents	0.5 mg/L

Iron	0.3 mg/L
Manganese	0.05 mg/L
Odor	3 threshold odor number
pH	6.5-8.5
Silver	0.10 mg/L
Sulfate	250 mg/L
Total Dissolved Solids	500 mg/L
Zinc	5 mg/L

Unregulated Drinking Water Contaminants

This list of contaminants which, at the time of publication, are not subject to any proposed or promulgated national primary drinking water regulation (NPDWRs), are known or anticipated to occur in public water systems, and may require regulations under the Safe Drinking Water Act (SDWA).

U.S. Department of Homeland Security
1111 Broadway,
Suite1200
Oakland, CA. 94607-4052

FEMA

August 31, 2007

CERTIFIED MAIL
RETURN RECEIPT REQUESTED

Jeff Pratt
Ventura County Department of Public Works
800 South Victoria Avenue
Ventura, CA 93009
(805) 654-2040

Dear Mr. Pratt:

This letter is in regard to the levees that are accredited on the effective Flood Insurance Rate Map (FIRM) and in the effective Flood Insurance Study (FIS) report for the Ventura County Watershed Protection District. These levees are identified on an enclosure to this letter. The U.S. Department of Homeland Security, Federal Emergency Management Agency (FEMA), is in the process of producing a countywide FIS report and Digital Flood Insurance Rate Map (DFIRM) for Ventura County, California. This effort is being undertaken as part of FEMA's Flood Map Modernization Program.

Flood hazard information presented on the effective FIRM and in the FIS report is based, in some areas, on flood protection provided by the levees identified on the enclosure. Based on the information available and on the mapping standards of the National Flood Insurance Program (NFIP) at the time that the FIS was performed, FEMA accredited the levees with providing protection from the flood that has a 1-percent-chance of being equaled or exceeded in any given year. The 1-percent-annual-chance flood also is referred to as the base flood.

For FEMA to continue to accredit the identified levees with providing protection from the base flood, the levees must meet the criteria of the Code of Federal Regulations, Title 44, Section 65.10 (44 CFR 65.10), titled "Mapping of Areas Protected by Levee Systems" (copy enclosed). In accordance with 44 CFR 65.10(a), it is the responsibility of the community or other party seeking recognition of a levee system, to provide the data defined and outlined within the regulation. Specifically, the design and construction data provided must be certified by a registered professional engineer or by a Federal agency with responsibility for levee design.

FEMA understands that it may take time to acquire and/or assemble the documentation necessary to fully comply with 44 CFR 65.10. Therefore, FEMA has incorporated a process into the schedule of Flood Map Modernization that, if needed, will provide the Ventura County Watershed Protection District with additional time to submit all the necessary documentation. Initiation of this process can take place only if the levee owner and a representative of each impacted community sign and return the enclosed agreement to the FEMA Region IX office within 90 days of the date of this letter (before November 30, 2007).

In addition, the following must be provided:

- A copy of the adopted operation and maintenance plan for the levee; and
- Records of levee maintenance and operation, as well as tests of the mechanized interior drainage systems, if applicable.

Completion and submittal of the agreement, as well as the operation and maintenance plan and records, will serve as an official request that FEMA label the levee as a Provisionally Accredited Levee (PAL) on the DFIRM and will serve as agreement that, to the best of your knowledge, the levee meets the criteria of 44 CFR 65.10. It is the responsibility of the levee owner to submit the data required by 44 CFR 65.10 before FEMA can accredit the levee as providing protection from the base flood. The completed package must be submitted to the FEMA Region IX office before November 30, 2007 for the levee to receive the PAL designation. Please note that a levee that has maintenance deficiencies is not eligible for PAL consideration.

By endorsing the enclosed agreement, you state that all the necessary documentation will be provided within 2-years to comply with 44 CFR 65.10; that is before September 1, 2009. If you are unable to submit all the documentation necessary to meet the criteria of 44 CFR 65.10 before this date, FEMA will initiate a map revision to redesignate certain areas on the landward side of the levee as floodprone.

Levees will be labeled as PALs during the 24-month period to convey to map users that levee certification verification is underway. FEMA recommends that the levee owner and the impacted communities implement outreach efforts to inform affected property owners that an assessment of the levee is underway. FEMA also encourages the purchase of flood insurance, even though coverage is not federally required for the areas landward of the accredited levee.

If the documentation necessary to fully comply with 44 CFR 65.10, including an existing operation and maintenance plan and record of on-site inspection, is readily available, please submit the data to this office. Upon receipt of your submittal, FEMA will review the data and determine whether the levee will continue to be accredited with providing protection from the base flood.

If the only grounds for the levee in question not currently meeting the 44 CFR 65.10 criteria or PAL requirements are **maintenance issues**, then the FEMA Region IX office must be contacted by letter to bring attention to the matter before the end of this 90-day period to submit the enclosed PAL agreement. If you notify FEMA that the levee has known maintenance deficiencies, then a 1-year correction period can be provided to remedy these deficiencies. This 1-year correction period would begin on November 30, 2007, if you notify FEMA within 90 days of the date of this letter. During the 1-year correction period, FEMA will move forward with the current flood hazard mapping project as if the areas landward of the levee is to be located in a Special Flood Hazard Area (SFHA); the mapped area subject to inundation by the base flood. However, FEMA will delay issuance of the Letter of Final Determination (LFD) and effective DFIRM until the 1-year correction period has elapsed.

For FEMA to remove the SFHA landward of the levee, the following requirements must be met within the 1-year correction period:

- All the criteria contained in 44 CFR 65.10 submitted to FEMA, <u>or</u>
- Submittal of the entire PAL application, including the following documentation:
  - An agreement signed by the community and/or levee owner stating that the PAL

designation is warranted because the levee meets the requirements of 44 CFR 65.10;
- o A copy of the adopted operation and maintenance plan for the levee; and
- o Records of levee maintenance and operation, as well as tests of the mechanized interior drainage systems, if applicable.

Once the 1-year correction period has expired, FEMA will assess any submitted data and determine whether any mapping revisions are necessary. If no data have been submitted within the 1-year correction period, or if the submitted data are determined inadequate, FEMA will issue the LFD and effective DFIRM to show the areas landward of a maintenance deficient levee as located in a SFHA. However, if all of the criteria of 44 CFR 65.10 or the entire PAL application is submitted before the 1-year correction period has elapsed, then FEMA will show the levee on the newly effective DFIRM as accredited or provisionally accredited, as applicable.

If you have additional questions regarding the specific submittal requirements, please contact Raymond T. Lenaburg, Senior Engineer, of my staff, either by telephone at (510) 627-7181 or by facsimile at (510) 627-7147 or by facsimile at (510) 627-7147. We look forward to working with you and community officials to address this important matter. If there is anything we can do to facilitate the submittal process, please let us know.

Sincerely,

For: Sally Ziolkowski, Director
Mitigation Division
FEMA Region IX

Letter of Agreement and Request for Provisionally Accredited Levee (PAL) Designation and Agreement to Provide Adequate Compliance with the Code of Federal Regulations, Title 44, Section 65.10 (44 CFR 65.10)

PAL Agreement Form

We, the undersigned, have received a letter from FEMA dated August 31, 2007 with an enclosed *"Levee Status Table"* and two enclosed documents titled *"Title 44 of the Code of Federal Regulations (CFR), Section 65.10 (44 CFR 65.10)"* and *"Requirements of 44 CFR Section 65.10: Mapping of Areas Protected by Levee Systems."* We understand that FEMA is in the process of providing an updated Flood Insurance Rate Map for Ventura County, California and that the flood hazards around levee(s) identified on the *Map* and *Levee Status Table* with ID numbers ____, ____, ____, will be remapped to reflect that these levees have been designated a PAL. This/these levee(s) or levee system(s) is/are also known as _____ _____.

To the best of our knowledge, the levee(s) identified above meet the criteria of 44 CFR 65.10 and has/have been maintained in accordance with an adopted operation and maintenance plan. For Scenario A (non-USACE Program) levees, this must be evidenced by an attached Operation and Maintenance Plan and records of levee maintenance and operation, as well as Test Records of Mechanized Interior Drainage System. We hereby submit to FEMA within 90 days (before November 30, 2007) our agreement to provide FEMA with all the necessary information to show that the levee(s) identified above comply with 44 CFR 65.10. We understand that this documentation will be provided before September 1, 2009. Providing the information described in 44 CFR 65.10 will allow FEMA to move forward with the flood mapping for Ventura County, California. We fully understand that if complete documentation of compliance with 44 CFR 65.10 is not provided within the designated timeframe of 24 months, FEMA will initiate a revision to the Flood Insurance Rate Map for Ventura County, California to redesignate the area as floodprone.

Levee Owner Representative (signature): _____ Date: _____

Levee Owner Representative (print name): _____

Community CEO (signature): _____ Date: _____

Community CEO (print name): _____

- Test Records of Mechanized Interior Drainage System

Instructions for Completing this Form:

- On this PAL Agreement Form, fill-in the levee ID numbers and levee(s) name/description for which the Provisionally Accredited Levee (PAL) designation is requested. A separate PAL Agreement Form is recommended for each unique levee owner/levee system. Make copies of this blank form to request PAL designation for multiple levee systems, as necessary.
- This document is available on-line (in a PDF format that can be filled-in electronically) via the link named "Generic PAL Agreement Form for Region IX" at http://rmc.mapmodteam.com/rmc9/Fact_Sheets.htm

City of Camarillo

Guidance for Flood Risk Analysis and Mapping

Levees

December 2020

FEMA

Requirements for the Federal Emergency Management Agency (FEMA) Risk Mapping, Assessment, and Planning (Risk MAP) Program are specified separately by statute, regulation, or FEMA policy (primarily the Standards for Flood Risk Analysis and Mapping). This document provides guidance to support the requirements and recommends approaches for effective and efficient implementation. The guidance, context, and other information in this document is not required unless it is codified separately in the aforementioned statute, regulation, or policy. Alternate approaches that comply with all requirements are acceptable.

For more information, please visit the FEMA Guidelines and Standards for Flood Risk Analysis and Mapping webpage (www.fema.gov/flood-maps/guidance-partners/guidelines-standards). Copies of the Standards for Flood Risk Analysis and Mapping policy, related guidance, technical references, and other information about the guidelines and standards development process are all available here. You can also search directly by document title at www.fema.gov/multimedia-library.

Table of Revisions

The following summary of changes details revisions to this document subsequent to its most recent version in November 2019.

Affected Section or Subsection	Date	Description
Section 1.2.4, 1.2.5	December 2020	Corrected minor alignment of wording.
Section 1.3.1	December 2020	Added more details to describe the National Levee Safety Program.
Section 4.1.10.2	December 2020	Updated web links.
Section 4.2 and subsections	December 2020	Updated to reflect FEMA and USACE data sharing processes.
Section 4.4, 6.12, and 6.19	December 2020	Minor wording revisions to address revised standards and introduction of evaluation lines for 2-D based floodways.
Section 5.5.2	December 2020	Corrected expiring PAL guidance to align with new standard.
Section 6.19	December 2020	Updated Zone D information and minor alignment of wording.
Section 6.21.1	December 2020	Added text for inclusion into the FIS when Freeboard Deficient approach is used and when Zone D is used.

1.0 Levees Overview

This consolidated guidance document was prepared for FEMA, as part of the Risk MAP program, to promote sound and consistent implementation of levee-related National Flood Insurance Program (NFIP) regulations and mapping program standards that apply to levees.

This guidance document is intended to provide current information on the mapping of levees and associated flood hazards. This document captures current standards and practices and, therefore, does not address all topics related to the identification of flood hazards and risks associated with levees.

Federal, State, and local officials have often considered levee systems an effective structural approach for reducing average annual flood losses. However, it is an approach that needs to be considered cautiously. Carefully engineered and well-maintained levees should divert floodflows as intended in their design and keep the areas landward of the levees dry if their structural integrity is not compromised, all elements of the system are functional, and the floodwaters do not overtop the structure. However, a primary drawback is that levees could lead to increased development of areas landward of the levees over time and thereby increase the exposure to catastrophic failures during extreme events (A Levee Policy for the National Flood Insurance Program, National Academy Press, 1982).

When it comes to working with communities on levee-related mapping projects or issues, FEMA shares a mission with its State agency partners, the U.S. Army Corps of Engineers (USACE), and other Federal agencies. That mission entails helping levee owners, flood control districts, community officials, floodplain managers, the media, and other stakeholders understand and properly communicate the risks associated with living and working landward of levees. Living with levees is a shared responsibility and local community officials should remain engaged in flood risk management activities. It is important for all stakeholders to know the risk; their role in helping to reduce that risk; and what specific actions they can take, including the purchase of flood insurance to further reduce the financial risk associated with living and working in levee-impacted areas. For more information, visit the Living with Levees portion of the FEMA website (https://www.fema.gov/flood-maps/living-levees).

The primary audiences for this guidance document are communities, regional entities, Tribal entities, and State agencies, including those participating in the Cooperating Technical Partners program (CTPs), FEMA Project Teams that are formed to carry out projects in support of the FEMA Regional Offices, and FEMA Regional Office and Headquarters staff. The FEMA Project Teams often include representatives of the FEMA Risk MAP providers. This guidance document is also intended for communities and local stakeholders involved in levee accreditation and the implementation of FEMA non-accredited levee analysis and mapping procedures.

The levee guidance in this document emphasizes the Risk MAP program vision of collaborating with local, regional, State, and Tribal entities throughout a watershed to deliver quality data that increases public awareness and leads to mitigation actions that reduce flood risk to life and property. To achieve this vision, FEMA transformed its historic documents for flood hazard

identification and mapping efforts into a more integrated process of identifying, assessing, communicating, planning, and mitigating flood-related risks aligned with the Risk MAP vision[1].

To accomplish this process, the appropriate analyses, mapping, and communication of risk of levee systems is necessary throughout the Risk MAP project lifecycle. FEMA has prepared this consolidated guidance in keeping with that responsibility.

1.1 Prior Guidance Documents

The consolidation of work that guided users through decades of levee-related procedures implemented during flood hazard mapping projects were incorporated into this guidance document. This is intended to promote sound and consistent implementation of policies, regulations, and standards for levee risk evaluation. This guidance enhances compliance with the Code of Federal Regulations; incorporates portions of Analysis and Mapping Procedures for Non-Accredited Levee Systems New Approach, (July 2013); and FEMA standards to facilitate implementation during flood hazard mapping projects. This guidance document has been prepared to expand on, and supersede, guidance provided in FEMA Operating Guidance (OG) 12-13; Procedure Memorandum (PM) Nos. 34, 43, 45, 51, 52, 53, and 63; and Appendix H of Guidelines and Specifications for Flood Hazard Mapping Partners. More details for each superseded guidance document are provided in each chapter of this document.

This guidance document does not supersede the following existing FEMA guidance documents:

- Analysis and Mapping Procedures for Non-Accredited Levee Systems New Approach.
- Guidance Document No. 29, Guidance for Flood Risk Analysis and Mapping: Levee Seclusion.
- Guidance Document No. 34, Guidance for Flood Risk Analysis and Mapping: Zone A99 and Zone AR Determinations.
- Guidance Document No. 72, Guidance for Flood Risk Analysis and Mapping: Levee-Specific Non-Regulatory Flood Risk Datasets.

These and additional mapping guidance and best practices can be accessed through the FEMA Guidelines and Standards for Flood Risk Analysis and Mapping webpage.

1.2 Flood Hazard Mapping and Levees

FEMA does not design, build, inspect, operate, maintain, or certify levees. However, as administrator of the NFIP, FEMA is responsible for accurately identifying flood hazards and communicating those hazards and risks to affected stakeholders.

Conditions in a community or watershed change over time; therefore, the need to update flood hazard information reflected on Flood Insurance Rate Maps (FIRMs) is assessed periodically to better reflect the current flood risk to people and property. FEMA updates FIRMs nationwide through the Risk MAP program. FEMA shows levee systems on the FIRM as being accredited,

[1] For more information on the Risk MAP program, see https://www.fema.gov/risk-mapping-assessment-and-planning-risk-map.

provisionally accredited, non-accredited, or in the process of being restored or constructed. FEMA designates the areas landward of the levees as Zone A, Zone AE, Zone AR, Zone A99, Zone D, Zone X (shaded), or Zone X depending on the status of the levee systems and the type of study performed. With new or updated FIRMs, community officials will have information to help them advise where and how to build more safely, and the public will understand their risk, allowing more informed decisions about reducing the risk to families, homes, and businesses.

Levees add complexity to an ongoing flood hazard study. To address the complexities that levees introduce, a FEMA Project Team should consider the presence of levees and appropriate mapping procedures as early in the study process as possible. Early consideration will help ensure that appropriate data collection and coordination occur. Subsections 1.2.1 through 1.2 5 briefly introduce the possible mapping options for levees.

1.2.1 Accredited Levee System

An accredited levee system is a system that FEMA has determined meets requirements of the NFIP regulations as cited in the Code of Federal Regulations (CFR) at Title 44, Chapter 1, Section 65.10 (44 CFR 65.10) and that FEMA has recognized on a FIRM as reducing the flood hazards posed by a base (1-percent-annual-chance) flood. This determination is based on a submittal, by or on behalf of a community, which includes 44 CFR 65.10–compliant design data and documentation, certified by a registered Professional Engineer (P.E.), and operations and maintenance documentation under the appropriate jurisdiction. FEMA strongly encourages flood insurance for all insurable structures in floodplains, including those in areas landward of levees.

FEMA accreditation of a levee system does not guarantee that the levee will provide flood hazard reduction to properties from flooding; therefore, FEMA has included a note on related FIRM panels that overtopping, or failure of an accredited levee system is possible. To mitigate flood risk in residual risk areas, property owners and residents are encouraged to consider flood insurance and floodproofing or other protective measures. Chapter 4 of this document provides detailed information on the mapping of accredited levee systems.

1.2.2 Provisionally Accredited Levee System

When the area impacted by an accredited levee system shown on an effective FIRM is in the process of being remapped, FEMA may ask the levee owner or community to provide data and documentation demonstrating the levee system still meets the requirements set forth in 44 CFR 65.10. To assist levee owners and communities, FEMA established the Provisionally Accredited Levee (PAL) designation as an option for mapping the area while providing levee owners or communities more time to gather the required data and documentation. The levee owner signs and submits an agreement to FEMA indicating the data and documentation required for compliance with 44 CFR 65.10 will be provided within 24 months of the 91st day following the date of the initial FEMA notification letter. FEMA places a note on the impacted FIRM panel(s) landward of the levee system to indicate FEMA has provisionally accredited the levee system and the designation of any existing Zone X (shaded) areas of flood hazard reduction due to levees is provisional. Chapter 5 of this document provides detailed information on the mapping of PALs.

1.2.3 Non-Accredited Levee System

Non-accredited levee systems are levee systems that do not meet the NFIP regulatory requirements of 44 CFR 65.10 and that are not shown on a FIRM as reducing the base flood hazard. FEMA recognizes that non-accredited levee systems do impact flood risk; for that reason, FEMA has developed analysis and mapping procedures for non-accredited levees that provide a suite of approaches for analyzing flood hazards landward of levee systems. Chapter 6 of this document provides detailed information on the mapping of non-accredited levee systems.

1.2.4 Levees Undergoing Restoration (Zone AR) and Undergoing Construction (Zone A99)

The NFIP regulations contain two provisions that help ameliorate the flood insurance impact on property owners during the restoration of non-accredited levee systems or construction of new levee systems. These are based on provisions of the National Flood Insurance Act of 1968, as amended, as cited in the United States Code (U.S.C.) at 42 U.S.C. 4014 (e) and 42 U.S.C. 4014(f). These provisions are intended to provide reduced flood insurance premium rates for insurable structures landward of levee system projects designed and intended for eventual accreditation. Under these provisions, a levee system undergoing construction, or restoration, but that cannot currently meet 44 CFR 65.10 requirements, is recognized by FEMA as providing some (less than the base flood) level of hazard reduction.

FEMA issues Flood Protection Restoration determinations, regulated through 44 CFR 65.14, in areas where a project is sufficiently underway to restore a levee system to meet 44 CFR 65.10 accreditation requirements. FEMA maps the areas landward of the levee system that is being restored as Zone AR on the FIRM and may present Base Flood Elevations (BFEs) representing the current hazard as if the levee system was not in place. The Zone AR determination may provide property owners with reduced flood insurance premium rates lower than rates in other mapped Special Flood Hazard Areas (SFHAs).

FEMA issues adequate progress determinations, regulated through 44 CFR 61.12, in areas where FEMA determines that a community has made adequate progress on a levee system construction or reconstruction project designed for flood hazard reduction. FEMA maps the areas landward of the levee system as SFHAs designated Zone A99 on the FIRM. The Zone A99 determination also provides flood insurance premium rates and floodplain management requirements that are generally less than those required in other SFHAs. The Zone A99 designation is used in place of a shaded Zone X accredited levee system recognized as reducing the flood hazards from a base designation for the landward area of the levee system. The horizontal extent of the Zone A99 would match the boundary extent of the potential area of reduced flood hazard that in the future would be adjusted to a shaded Zone X accredited levee system recognized as reducing the flood hazards from a base flood designation.

Detailed information on Flood Protection Restoration and Adequate Progress determinations is provided in FEMA Guidance Document No. 34, Guidance for Flood Risk Analysis and Mapping: Zone A99 and Zone AR Determinations. Guidance Document No. 34 is accessible through the FEMA Guidelines and Standards for Flood Risk Analysis and Mapping webpage.

1.2.5 Levee Seclusion Mapping

In March 2011, FEMA committed to updating the way flood hazards for non-accredited levee systems were analyzed and mapped. As a result, some in-progress FIRM updates that included levee systems were delayed or otherwise impacted while FEMA developed the analysis and mapping approach for non-accredited levees. FEMA developed the levee seclusion mapping approach as a project management solution to allow the release of the FIRM updates for those portions of the community outside of the levee-impacted area. Through the levee seclusion mapping approach, FEMA maintains the flood hazard information as depicted on the current effective FIRM (the FIRM in effect before the in-progress update) with map notes explaining that the flood hazard information in these areas will be updated after FEMA applies an updated levee analysis and mapping approach. Levee seclusion was not intended to be a long-term mapping approach and was not anticipated to be implemented on any mapping projects initiated after July 2013. Justification to use Seclusion mapping on the FIRM panel must be coordinated with and approved by the FEMA Region and FEMA Headquarters. Detailed information on seclusion is provided in FEMA Guidance Document No. 29, Guidance for Flood Risk Analysis and Mapping: Levee Seclusion, which is accessible through the FEMA Guidelines and Standards for Flood Risk Analysis and Mapping webpage.

1.3 Summary of Recent Legislation and Recommendations

This section summarizes some recent legislation and recommendations related to managing and assessing levee systems.

1.3.1 Water Resources Development Act of 2007

Title IX of the Water Resources Development Act (WRDA) 2007, the National Levee Safety Act of 2007, as amended and codified in 33 USC Chapter 46, includes activities in support of establishing a National Levee Safety Program to be led by USACE in cooperation with FEMA. USACE and FEMA have been working within existing appropriations to develop some of the technical and communication building blocks necessary for an effective National Levee Safety Program. USACE and FEMA remain fully committed to working within available appropriations to continue to make progress on achieving the overall objectives of the National Levee Safety Program. The National Levee Safety Act requires: 1) establishment of the Committee on Levee Safety as an all non-federal advisory body; 2) a database with an inventory of the Nation's levees; 3) a one-time review of all levees in the National Levee Database (NLD); 4) carrying out a levee safety initiative that establishes technical guidelines, creates and supports state/regional/tribal levee safety programs, provides technical assistance broadly and funding for specific items and improves public awareness of levee-related issues; and, 5) specified reports. Recommendations leading up to this legislation can be found on the USACE website (www.usace.army.mil/National-Levee-Safety/).

1.3.2 Flood Protection Structure Accreditation Task Force

The USACE and FEMA formed the Flood Protection Structure Accreditation Task Force (Task Force) in accordance with Section 100226 of Public Law (P.L.) 112-141. The primary charge of the Task Force was to align agency processes, so information collected for either program can be used interchangeably and to align the information and data collected by USACE, so it is sufficient to satisfy NFIP accreditation requirements. The Task Force resulted in a list of recommendations

and a formal memorandum of understanding signed by USACE and FEMA committing to establishing a coordinated approach for levee activities that is aligned with policies and goals of both agencies to promote life safety, flood risk reduction, risk communication, and sound national investments. The final Task Force report and memorandum of understanding can be found at https://www.usace.army.mil/Missions/Civil-Works/Levee-Safety-Program/Task-Force/.

1.3.3 National Academy of Science Recommendations

The National Research Council (NRC) document titled A Levee Policy for the National Flood Insurance Program, published in 1982, made recommendations to FEMA for a comprehensive levee policy for use in administering floodplain management, insurance, and hazard mapping aspects of the NFIP. The document addressed five areas that NRC deemed critical to a levee policy: (1) Minimum design standards; (2) Inspection and evaluation to be conducted by FEMA to assure conformance with minimum design standards at the time a levee is recognized in the program; (3) Requirements FEMA should place on communities with recognized levees; (4) Estimation of risk in areas landward of levees for use in setting insurance rates; and (5) Floodplain mapping of levee-impacted areas to portray SFHAs, degree of flood risk, and evacuation routes.

The National Academy of Sciences (NAS) document titled Levees and the National Flood Insurance Program, Improving Policies and Practices, published in 2013, examines the way levees are addressed in the NFIP and provides advice as to what actions might be taken to improve program efficiency and effectiveness. The NAS document includes 11 recommendations and 10 conclusions to improve the policies and practices related to levees and the NFIP. Additional information on the NAS document is accessible through the NAS website at https://nas-sites.org/levees/. While FEMA is making progress toward achieving some of the goals and objectives, this guidance document does not address the modern risk-informed analysis recommended in the NAS document.

1.4 Levee-Related Communication and Community Engagement

To appropriately analyze and map the flood hazards in levee-impacted areas, FEMA will coordinate with communities during the Discovery Phase of a Flood Risk project, and throughout the project lifecycle as necessary, to understand the location and impacts of levee systems. The current, effective FIRMs may inadvertently represent levee systems as providing flood hazard reduction or other impacts to the conveyance of floodwaters, and as such, may indicate a lesser flood hazard and corresponding risk than what may actually exist in these areas. Because communities and property owners may not be fully aware of the risk associated with levee systems, coordination with local stakeholders is essential to identify, analyze, and map the flood hazards associated with levee systems and to provide relevant information and tools to help them understand their flood risk and mitigation opportunities in these areas.

FEMA developed the Risk Communications and Risk MAP Playbook, also known as the Community Engagement and Risk Communication (CERC) Playbook, to focus on the value of outreach and community engagement in ensuring the successful delivery of the Risk MAP program goals and demonstrating how communication can facilitate an understanding of the value of mitigation and the importance of resilience. The Playbook provides guidance to FEMA, FEMA Risk MAP providers (primarily, the Production and Technical Services [PTS] and CERC providers), and CTPs on developing approaches that will ultimately motivate communities toward

mitigation action throughout the Risk MAP lifecycle, including those communities impacted by levees.

Section 5 of the Playbook, "Risk Communication for Communities with Levees", provides guidance on FEMA's role regarding levees, how that role intersects with the roles of other agencies; and how to effectively communicate flood risk with respect to levees. The levee section of the Playbook includes information on the following topics:

- Levee Systems: Who Does What?
- What Is Risk Communication in Relation to Levees?
- Why and How Does FEMA Map Flood Hazards for Levee-Impacted Areas?
- Risk Messaging for Levees
- Developing your Community Engagement Plan
- Building Resiliency

Project Team members should refer to the CERC Playbook for additional information about stakeholder engagement and links to examples, tools, and templates. The CERC Playbook can be accessed through the password-protected Risk Management Directorate SharePoint Portal or by contacting the FEMA Project Officer.

This guidance document focuses on mapping guidance and therefore does not cover risk communication in detail, although these are important portions of the flood hazard mapping project lifecycle.

1.5 Chapter Overviews

Primary topics covered by this guidance document include the collection and management of levee data; procedures for addressing accreditation, PALs, and non-accredited levees; addressing the topic of evaluating and mapping flood hazards landward of non-levee features; and coordination with USACE and other Federal agencies. Additional summary information for each chapter is provided in Subsections 1.5.1 through 1.5.8

1.5.1 Chapter 2, Glossary of Levee Terms

The glossary in Chapter 2 contains levee terminology to be used throughout this guidance document.

1.5.2 Chapter 3, Levee Data Inventory

Chapter 3 provides an overview and brief history of FEMA historic levee inventory systems. The chapter introduces FEMA's overall mission with early identification of levees, levee data tracking, inventory, mapping, and coordination/cooperation with USACE in the direction toward a unified national levee database. Chapter 3 provides guidance for populating and maintaining the FEMA accreditation status tracking system, the NLD, and National Flood Hazard Layer (NFHL).

1.5.3 Chapter 4, Accredited Levee Systems

Chapter 4 provides focused guidance on levee accreditation, leveraging the requirements in 44 CFR 65.10 and the transformation of PM 45, Revisions to Accredited Levee and Provisionally Accredited Levee Notation, issued on May 12, 2008; and PM 63, Guidance for Reviewing Levee Accreditation Submittals, issued on September 2, 2010. In addition to the transformed guidance, Chapter 4 includes clarifications and best practices that have been collected since the implementation of PMs 45 and 63.

1.5.4 Chapter 5, Provisionally Accredited Levees

Chapter 5 provides guidance to Project Team members (FEMA, FEMA Risk MAP providers, CTPs, and CTP subcontractors) on implementing the PAL process. This chapter is a transformation and revision of PM 43, Guidelines for Identifying Provisionally Accredited Levees, issued on September 25, 2006; PM 45, Revisions to Accredited Levee and Provisionally Accredited Levee Notation, issued on May 12, 2008; and PM 53, Guidelines for Notification and Mapping of Expiring Provisionally Accredited Levee Designations, issued on April 24, 2009.

1.5.5 Chapter 6, Non-Accredited Levees

Chapter 6 provides guidance to FEMA Regional Office staff, FEMA Risk MAP providers, CTPs, and CTP subcontractors involved in performing flood hazard mapping projects where non-accredited levee systems have been identified. This chapter follows the levee analysis and mapping procedures described in OG 12-13, Non-Accredited Levee Analysis and Mapping Guidance, dated September 2013.

1.5.6 Chapter 7, Non-Levee Features

Chapter 7 recommends actions that would help ensure adequate identification, analysis, and mapping of potential flood hazards around non-levee features. This chapter is a transformation and revision of PM 51, Guidance for Mapping of Non-Levee Embankments Previously Identified as Accredited, issued on February 27, 2009.

1.5.7 Chapter 8, FEMA and Other Federal Agency Coordination

Chapter 8 provides guidance to FEMA Regional Office staff, Risk MAP providers, and CTPs performing flood hazard mapping projects where other Federal agencies may have a role. These potential roles could include policy development, actual mapping actions, and accreditation efforts involving levees. In addition, mitigation and outreach activities may involve other Federal agencies.

2.0 Glossary

Key levee terms used throughout this guidance document. are defined in Table 1.

Table 1: Levee Terms

Levee Term	Description
Accredited Levee System	A levee system shown on a FIRM that is recognized as reducing the flood hazards posed by a base flood. This determination is based on the submittal of data and documentation as required by 44 CFR 65.10. The area landward of an accredited levee system is shown as Zone X (shaded) on the FIRM except for areas of residual flooding, such as ponding areas, which are shown as SFHA.
Berms	Horizontal strips or shelves of material built contiguous to the base of either side of levee embankments for the purpose of providing risk reduction from underseepage or erosion or increasing the stability of the slopes of the earthen embankment.
Certification	As stated in 44 CFR 65.2(b), certification of analyses is a statement that the analyses have been performed correctly and in accordance with sound engineering practices. Certification of structural works is a statement that works are designed in accordance with sound engineering practices to provide risk reduction from the base flood. Certification of "as built" conditions is a statement that the structure(s) has been built according to the plans being certified is in place and is fully functioning. Certification documentation is the responsibility of the local project sponsor.
Closure Devices	Any movable and essentially watertight barriers, used during flood periods to close openings in levee systems, securing but not increasing the levee systems' design level of risk reduction. Must be structural parts of the system during operation and designed according to sound engineering practice.
Erosion	The wearing away of land masses through gradual natural processes or catastrophic events.
Flood Risk	The risk of flooding in a leveed area that remains at any point in time after accounting for the flood risk reduction contributed by the levee system. Risk is a measure of the probability and severity of undesirable consequences. Flood risk is comprised of three parts: (1) the likelihood of occurrence of an event (e.g., flood, earthquake, etc.), (2) the likelihood associated with the performance of the levee system (e.g., levee breach, closure malfunction, overtopping, etc.), and (3) the magnitude of the consequences resulting from inundation of the levee impacted

Levee Term	Description
	area during that event (e.g., life loss, economic damages, environmental damages, etc.).
Floodwall	A designed structural wall constructed adjacent to shorelines for the purpose of reducing flooding of property on the landward side of the wall. Floodwalls are normally constructed in lieu of or to supplement levees where the land required for levee construction is too expensive or not available.
Freeboard	A factor of safety usually expressed in feet above a flood level for purposes of floodplain management. ”Freeboard’’ tends to compensate for the many unknown factors that could contribute to flood heights greater than the height calculated for a selected size flood and floodway conditions, such as wave action, bridge openings, and the hydrological effect of urbanization of the watershed. At times, overbuild to account for long-term settlement and incrementing the height to ensure maintenance access during flood events is referred to as freeboard as well. For levees and purposes of the NFIP, this is the vertical distance between the top of a levee and the water level that can be expected during the base flood.
Freeboard Deficient Procedure	Non-accredited levee analysis and mapping procedure that is applicable if the freeboard standard is not met, but the top of levee is above the base flood. A Freeboard Deficient levee reach must meet the structural requirements of 44 CFR 65.10 and have documented operation, maintenance, and emergency preparedness plans. Freeboard Deficient Levee reaches differ from an accredited levee system because they are part of a levee system that as a whole cannot meet accreditation requirements and because they cannot meet the regulatory freeboard standard.
Gravity outlets	Culverts, conduits, or other similar conveyance openings through embankments or floodwalls that permit discharge of interior floodwaters by gravity when the outlets are above exterior water levels. Gravity outlets are equipped with gates to prevent flows from entering the levee impacted area during time of high exterior stages.
Hazard	An event or physical condition that has the potential to cause fatalities, injuries, property damage, infrastructure damage, agricultural loss, damage to the environment, interruption of business, and other types of loss or harm.
Hydraulic Analysis	An engineering analysis of a flooding source carried out to determine how flood waters will move within the system in response to differing discharge quantities.

Levee Term	Description
Hydraulic Independence	Two levees or levee reaches are considered hydraulically independent when their level of flood hazard reduction functions independently from the other; their corresponding levee impacted areas are not identical; and if one breaches or overtops, the structural integrity of the other levee/levee reach is not adversely impacted.
Hydraulically Insignificant	For mapping purposes, a structure is considered hydraulically insignificant if, during a 1-percent–annual-chance flood event, the peak water-surface elevations landward of the structure may be the same regardless of whether the structure was in place.
Inspection	A visual assessment of physical features of a levee system to determine the general condition and operability of the levee. This may include operation and mechanical features such as pumps or gates.
Interior Drainage	Natural or modified removal of runoff within an area landward of a levee.
Interior Drainage Systems	Systems associated with levee systems that usually include storage areas, gravity outlets, pumping stations, or a combination thereof to control interior drainage.
Levee	Per 44 CFR 59.1, a manmade structure, usually an earthen embankment, designed and constructed in accordance with sound engineering practices to contain, control, or divert the flow of water to reduce flood hazards posed by temporary flooding.
Leveed Area	A spatial feature in the National Levee Database defined by the lands from which floodwater is excluded by the levee system.
Levee Breach	A rupture, break, or gap in a levee system that causes flooding in the area landward of the levee system and may be due to overtopping or levee feature failure.
Levee Feature	A structure that is critical to the functioning of a levee system, including: (A) an embankment section; (B) a floodwall section; (C) a closure structure; (D) a pumping station; (E) an interior drainage work; and (F) a flood damage reduction channel.
Levee Impacted Area (*for base flood*)	The area landward of a levee system that would be inundated by the corresponding base flood if the flood hazard reduction effect of the levee system is not considered. Often, this area will be identified by applying the Natural Valley Procedure for the levee system.

Levee Term	Description
Levee Owner	A federal or state agency, a water management or flood control district, a local community, a levee district, a nonpublic organization, or an individual considered the proprietor of a levee. The levee owner is responsible for administering the operations, maintenance, and emergency preparedness plans for the levee system. Often referred to as levee sponsor.
Levee Reach	A levee reach is a portion of a levee system (usually a length of a levee) that may be considered for analysis purposes to have approximately uniform representative properties. A levee reach is a unique component having properties different than other reaches of the levee system and may be used to evaluate the performance of a portion of the levee system. No minimum or maximum length is associated with a reach. Any continuous section of a levee to which a single analysis and mapping procedure may be considered as a reach.
Levee Segment	A discrete portion of a levee system that is operated and maintained by a single entity. A levee segment can be comprised of a single levee reach or multiple reaches. A levee segment may comprise one or more levee feature.
Levee System	A flood hazard-reduction system that consists of one or more levee segments/reaches and other features, such as floodwalls and pump stations, which are interconnected and necessary to ensure exclusion of the design flood from the associated hydraulically independent levee impacted area, and which are constructed and operated in accordance with sound engineering practices.
Line of Flood Hazard Reduction	The centerline of the levee segments/reaches which exclude floodwaters from the base flood event from the levee impacted area.
Local Levee Partnership Team (LLPT)	A workgroup that is facilitated by FEMA when a levee system will be analyzed by levee analysis and mapping procedures for non-accredited levees. The primary function of this group is to share information/data and identify options based on stakeholder roles and knowledge.

Levee Term	Description
National Levee Database (NLD)	The NLD, developed by the USACE in cooperation with FEMA, is a dynamic, searchable inventory of information for all levee systems in the nation. The database contains information to facilitate and link activities, such as flood risk communication, levee system evaluation for the NFIP, levee system inspections, floodplain management, and risk assessments. The NLD continues to be a dynamic database with ongoing efforts to add levee data from federal agencies, states and tribes.
Natural Valley Procedure	Non-accredited levee procedure that can be applied to all non-accredited levee reaches. The Natural Valley Procedure is used in two ways: first landward of the entire levee system to determine the outer limits of any levee impacted Zone D areas, and second as a potential procedure applied to individual levee reaches to determine the SFHA on the landward side of the levee reach. Several factors are considered when determining whether to use the Natural Valley Procedure to determine the SFHA: • The levee reach does not significantly obstruct the flow of water; Data necessary for more complex methods is not and will not be available in the near term; or • The community (or tribal entity, when appropriate) provides feedback that it is the acceptable procedure to use. For riverine levee systems, the Natural Valley Procedure reflects the levee geometry in the hydraulic model but allows water to flow on either side of the levee. For coastal levee systems, the Natural Valley Procedure reflects the levee geometry, and consideration is given as to how the levee system impacts wave propagation.
Non-Accredited Levee System	A levee system that does not meet the requirements in the NFIP regulations at Title 44, Chapter 1, Section 65.10 of the Code of Federal Regulations (44 CFR 65.10), Mapping of Areas Protected by Levee Systems, and is not shown on a FIRM as reducing the base flood hazards.
Non-levee Feature	A physical feature that is not designed, constructed, operated, or maintained as a flood control structure, but may inadvertently confine flow during some flood events.

Levee Term	Description
Non-levee Reach	A form of manmade high ground which a levee system or segment/reach ties into, whose existence and performance is necessary for excluding floodwaters from the levee impacted area.
Overtopping	A condition that occurs when water levels, including any wave or run-up factors, exceed the top elevation of a levee system and flow into areas landward of the levee system. Levee system may be damaged and/or compromised.
Overtopping Procedure	Non-accredited levee procedure is applicable when the base flood is above the levee crest for a reach, and the community or levee owner has provided appropriate technical justification that the base flood event will not cause a levee breach. In addition to the structural standards established in 44 CFR 65.10, it is expected that more detailed structural analysis will be required to justify that the levee system can sustain the base flood. As with a Sound Reach and Freeboard Deficient levee reach, an operations and maintenance plan and documentation of inspection are required.
Piping	The result of water seepage that progressively erodes and washes away soil particles, leaving large voids in the soil. Removal of soil through sand boils by piping or internal erosion damages levees, their foundations, or both, which may result in settlement and has the potential to cause catastrophic failures of levees.
Ponding	The result of runoff or flows collecting in a depression that may have no outlet, subterranean outlets, rim outlets, or manmade outlets such as culverts or pumping stations. Impoundments landward of manmade obstructions are included in this type of shallow flooding as long as they are not backwater from a defined channel or do not exceed 3.0 feet in depth.
Provisionally Accredited Levee (PAL)	A designation for a levee system that FEMA has previously accredited with reducing the flood hazards associated with a base flood on an effective FIRM, and for which FEMA is awaiting data and/or documentation that will demonstrate the levee system's compliance with the NFIP regulatory criteria of 44 CFR 65.10.
Pumping Stations	Pumps located at or near the levee system to discharge interior drainage over or through the levees or floodwalls (or through pressure lines) when free outflow through gravity outlets is prevented by high exterior stages.

Levee Term	Description
Rehabilitation	The term rehabilitation means the repair, replacement, reconstruction, or reconfiguration of a levee system, including a setback levee.
Residual Risk (or Flood risk)	The flood risk (probability of capacity exceedance or failure and the associated consequences) that remains after the flood risk management measure is implemented.
Ring Levees	Levees that completely encircle or “ring” an area subject to inundation from all directions.
Risk Assessment	A systematic, evidence-based approach for quantifying and describing the nature, likelihood, and magnitude of risk.
Setback Levees	Levees that are built landward of existing levees, usually because the existing levees have suffered distress or are in some way being endangered, as by river migration.
Shallow Flooding	Flat areas where a lack of channels prevents water from draining away easily. Shallow flood types fall into three categories: sheet flow, ponding, and urban drainage. For the purposes of the NFIP, shallow flooding is distinguishable from riverine or coastal flooding because it generally occurs in an area where there is no channel or identifiable flow path.
Sound Reach Procedure	A reach that has been designed, constructed, and maintained to withstand the flood hazards posed by a base flood, in accordance with the standards in 44 CFR 65.10 of the NFIP regulations, but is part of a system that cannot be accredited.
Structural-Based Inundation Procedure	Non-accredited levee analysis and mapping procedure applicable to some levee systems having reaches with either structural deficiencies that are known or structural integrity that is unknown (a common occurrence for older levee systems). For these levee reaches, FEMA will rely on modeling of breaches along the levee reach. It is not possible to predict the exact location of a levee breach. This procedure, therefore, does not predict the probability of failure at any breach location, nor does it provide a specific determination or evaluation of the overall levee system performance or require a determination of the likely failure mechanism. The procedure instead results in the development of a levee reach-specific SFHA that might occur as a result of potential breaches along a particular levee reach during the base flood. To determine this SFHA, possible locations of system breaches, geometry, and failure duration will be considered.

Levee Term	Description
Zone A99	As defined in 44 CFR 61.12, areas subject to inundation by the base flood event, but which will ultimately be accredited upon completion of an under-construction levee system. These are areas of special flood hazard where enough progress has been made on the construction of a levee system, such as dikes, dams, and levees, to consider it complete for insurance rating purposes. Zone A99 may only be used when the levee system has reached specified statutory progress toward completion. No BFEs or depths are shown. Mandatory flood insurance purchase requirements and floodplain management standards apply.
Zone AR	As defined in 44 CFR 61.12, areas that result from the new non-accredited status of a previously accredited levee system that is determined to be in the process of being restored to provide base flood risk reduction. Mandatory flood insurance purchase requirements and floodplain management standards apply.
Zone D	An area of possible, but undetermined flood hazard. When analyzing and mapping areas landward of non-accredited levee systems, a Zone D may represent areas landward of a non-accredited levee, within the natural valley footprint, that are not depicted as SFHA resulting from freeboard deficient, sound reach, overtopping, and/or structural-based inundation procedures. The Zone D designation is used for non-accredited systems instead of the Zone X (shaded) designation because the flood hazard potential is more uncertain and possibly greater.

3.0 Levee Data Inventory

The construction of flood hazard-reduction structures, such as levees and floodwalls, has had a significant effect on flood-prone areas throughout the United States. These structures are of particular importance in identifying flood hazards and risks to lives and property. As such, FEMA and USACE share a common interest in managing and administering levee information and data throughout the Nation. This chapter provides background on previous FEMA levee inventory systems; introduces FEMA's overall mission with regard to identification of levees, levee data tracking, inventory, mapping, and coordination/cooperation with USACE on the development of a unified national levee database; and provides guidance for populating and maintaining the FEMA accreditation status tracking system, NLD, and NFHL database.

3.1 Background

With the enactment of WRDA in 2007, the U.S. Congress directed USACE to develop a national database for levee data and information. USACE developed the database model for the NLD to meet that long-term goal. FEMA initially used a simplified subset of the NLD database schema to compile a midterm levee inventory database for internal use. The two agencies synchronized the two databases to track information specific to their respective agencies with the goal to merge the two into one authoritative database. USACE focused on levees as part of their agency Levee

Safety Program while FEMA's interest was to inventory all levees to identify those affecting flood hazard mapping efforts as part of the NFIP.

The FEMA midterm levee inventory database contained data gathered for many levees that were designed to provide flood hazard reduction from the base flood. This standard is the minimum level of flood hazard reduction that is recognized by the NFIP. However, the database also frequently included data for levees that did not meet this minimum NFIP criterion for accreditation, as well as agricultural levees and levees of small and potentially less significant nature.

Beginning in 2012, FEMA and USACE formed a team of levee Subject Matter Experts (SMEs) to collaboratively merge the FEMA inventory into the NLD. The FEMA/USACE team completed the effort to integrate the two databases in May 2016.

3.2 National Levee Database

USACE and FEMA envision the NLD to be the main repository for comprehensive information about all levees and floodwalls in the United States. The NLD is a dynamic database, with USACE and FEMA staff continuously updating its content and adding levee data from other Federal agencies, States agencies, and communities. The NLD contains various levels of information for levees within the USACE Levee Safety Program and non-USACE Program levees, with information from FEMA and other organizations.

The NLD includes attributes of levees and floodwalls relevant to design, construction, operations, maintenance, repair, inspections, and performance. The NLD will facilitate linking levee safety activities, such as flood risk communication, levee system evaluations for the NFIP, levee system inspections, floodplain management, and risk assessments. Most of the information in the NLD is publicly available. Only information deemed sensitive from a security standpoint is not publicly available. For information on accessing the non-public NLD, interested parties should consult with FEMA Project Officer, other FEMA Regional Office staff, or the designated mapping partner responsible for supporting the Region with levee inventory and tracking.

3.3 Identification and Mapping of Levees in Flood Hazard Studies and Map Revisions

An important step in identifying and mapping areas impacted by levee systems is to first consult with FEMA Regional Office staff that are not part of the FEMA Project Team, as well as the local community Floodplain Administrator (FPA) and the State. When the Project Team identifies a potential flood-control structure, the assigned team member should evaluate the structure to determine whether it can be considered a levee and is subject to the procedures described in this guidance document. FEMA will only consider a structure to be a levee when it can be demonstrated that the structure was designed and has been operated and maintained as a levee. FEMA verifies whether a structure meets this definition of a levee by coordinating with community officials and levee owners, and by reviewing available levee data and documentation.

The FEMA Region and other Project Team members will be able to use the available accreditation status tracking systems to provide details about levee systems, special situations, or any additional analysis or outreach that may be necessary. The local FPA may have knowledge of any newly constructed flood-control projects that may not yet be inventoried by FEMA or USACE. The local FPA also may be able to provide updates to the data FEMA and USACE have already

inventoried. Items that the Project Team should consider when determining whether the flood hazard mapping project will impact any levees include, but are not limited to, those listed below (in no particular order of priority).

- Levee features in the S_Levee feature class of the NFHL
- Levee symbology on the effective FIRM
- Levee features USACE NLD database
- Local data for new flood control projects recently completed that may not already be inventoried by FEMA or USACE
- Effective FEMA accreditation status of all existing levees in the project footprint
- Any existing, pending, or missing 44 CFR 65.10 certification data and documentation
- Non-accredited levees that may require new/updated levee analysis and mapping procedures for non-accredited levees
- Topographic data, such as Light Detection and Ranging (LiDAR)-generated data and U.S. Geological Survey (USGS) quadrangles, that may show potential flood-control structures

If discrepancies exist between the NFHL and the NLD, the assigned Project Team member should coordinate with the FEMA regional levee data leads, USACE District, and the local FPA to determine the best available data.

The FEMA-led Project Team or mapping partner should complete the research and identification of levees early on during the project. Early identification of levees allows the Project Team or mapping partner time to reach out to the community, or to another party seeking recognition of levee, to collect information and discuss options, responsibilities, and expectations regarding mapping of the levee system(s) and the levee-impacted area(s) on the FIRM.

The Project Team or mapping partner is to examine the current effective FIRM, as well as the existing effective S_Levee feature class in the NFHL database and compare it to the NLD to resolve any discrepancies. The Project Team or mapping partner can download the current effective NFHL data from the FEMA Flood Map Service Center (MSC) for counties that have been converted to a digital FIRM format. For levees that were not previously mapped on the FIRM, or inventoried in the NLD, the assigned Project Team member or mapping partner must input a new entry in S_Levee, with relevant information collected and recorded, as described in Section 3.6 of this document.

The assigned Project Team member or mapping partner should next examine the levee features in the NLD that are located within the project footprint, making note of any spatial misalignments and additional/missing features between the NFHL and the NLD. The assigned Project Team member or mapping partner is to verify and correct these discrepancies in the production data through the use of best available orthoimagery, topographic data, and online web mapping data (such as Google Earth) and through engagement with local community officials. The assigned team member or partner is to report the updated levee mapping to FEMA as described in Section 3.6 of this document. The Project Team or mapping partner is to verify any changes to the USACE Program Levee alignments with the responsible USACE District first.

When levees are identified, FEMA is to inform the community of the data requirements for FEMA to recognize on the FIRM a levee with reducing the base flood hazard. In accordance with 44 CFR 65.10(a), it is the responsibility of the community or other party seeking recognition of a levee system at the time of a flood hazard study or restudy to provide the data outlined in 44 CFR 65.10. (See Chapter 4 – Levee Accreditation of this document.)

FEMA will update the FIRMs to depict the hazard associated with the levee based on the data and documentation provided (if any) by the community, levee owner, or certifying engineer. In addition, FEMA will notify the community or party seeking recognition of the data collection period to provide information regarding the hazards associated with the levee system.

The specific data requirements and the length of the collection time period depend on the level of intended flood hazard reduction and the mapping path forward. The data and timelines are discussed in Chapter 4 – Accredited Levee Systems, Chapter 5 – Provisionally Accredited Levee Systems, and Chapter 6 – Non-Accredited Levee Systems. At any point, a levee owner may choose to submit a map revision following the MT-2 process regarding the submittal of data and documentation and updates to the flood hazards on the FIRMs.

3.4 FEMA Regulatory Levee Data

Once the Project Team or mapping partner has identified and researched all flood-control structures in the project areas, as discussed in Section 3.3, the team or partner uses the S_Levee table in the FIRM database to store the spatial features, and whether they have been demonstrated to meet NFIP requirements in 44 CFR 65.10. The Project Team or mapping partner will symbolize all flood control features inventoried in the S_Levee table on the FIRM panel as outlined in Flood Insurance Rate Map (FIRM) Panel Technical Reference: Format for Flood Insurance Rate Maps and noted as accredited or non-accredited.

The accreditation status of any levee in the NFHL and on the FIRM panel is only as current as the date of the effective study. At this time, FEMA does not define a set time period in which a certification of data for a levee remains valid for accreditation. The certifying engineer may provide a timeframe for which the certification of data for a levee is valid. When a map action is initiated to revise a current effective FIRM panel containing a levee, the assigned Project Team member or mapping partner will need to revisit the certification and subsequent accreditation status of that levee. Further discussion regarding the continued accreditation of levees is provided in Chapter 4 of this document.

Inside the FIRM database, the assigned Project Team member or mapping partner must include the levee System ID from the NLD in the S_Levee table. For more information on populating the NLD System ID in the S_Levee table, the team members or partner should refer to Technical Reference: Flood Insurance Rate Map (FIRM) Database. It is critical that this NLD System ID is correctly attributed in the S_Levee table to maintain the linkage to the detailed levee records maintained in the FEMA accreditation status tracking systems and the NLD. The Project Team or mapping partner should always depict accredited levee systems on the FIRM with a “Zone X – Area with Reduced Flood Risk Due to Levee” flood hazard zone on the landward side of the levee. In addition, the Project Team or mapping partner should show all accredited levees, PALs, and non-accredited levees (all other levees shown on the FIRM with a levee symbol) in Table 9 of the current, effective Flood Insurance Study (FIS) Report(s). The team or partner shall ensure that

the information in Table 9 matches the data populated in the S_Levee table. For more information on including levee information in the FIS Report, Project Team members or partners should refer to the current version of Flood Insurance Study (FIS) Report Technical Reference: Preparing FIS Reports.

The Technical References cited above are accessible from the FEMA Technical References webpage (https://www.fema.gov/media-library/assets/documents/34519).

If discrepancies exist between the FIRM database and the NLD, the assigned Project Team member must correct the discrepancies as part of the current map action so that the FIRM database, and subsequent NFHL, represent the most accurate levee alignment and inventory. Reporting requirements for the updated levee mapping are described in Section 3.6 of this document.

3.5 Tracking Levee Accreditation Status

Tracking specific levee information is critical to meeting FEMA program goals. As part of the NLD and subsequent tracking systems, FEMA maintains information about all levee systems such as:

- Current accreditation status on the effective FIRM
- Long-term levee project planning and prioritization
- Levee-related FIRM mapping issues
- 44 CFR 65.10 certification records
- Levee-related risk assessments
- Ongoing levee studies
- Local ownership, media, and political information

The NLD can be accessed and edited by designated USACE staff, FEMA staff, and FEMA Regional levee SMEs who help to maintain the database while keeping it synched with NFHL databases.

3.6 Reporting Levee System Updates

The FEMA mapping partner or Project Team member producing the updated FIRM is expected to have detailed knowledge of whether the map update includes any updates to levee system reach alignments or changes to levee accreditation status. The process of researching levees for flood studies and map revisions was described in Section 3.3 of this document.

When new levee features are added to the inventory or existing levee data is modified, the mapping partner or Project Member must incorporate the updates into the FIRM database and then into the NFHL database. The mapping partner and Project Team is to ensure that all updates are coordinated with the FEMA Region and designated levee SMEs to incorporate appropriate updates into the NLD, and FEMA tracking systems.

Specific questions related to levee data updates exist in the Key Decision Point (KDP) questionnaires. Accurate and complete answers to these levee questions are very important. The

KDP levee information provided will give the FEMA Region staff and their designated Levee Project Monitors visibility on any updates that need to take place in the national levee data inventory and tracking systems. More detailed information on the KDP process and copies of the questionnaires are provided in FEMA Guidance Document No. 35, Guidance for Flood Risk Analysis and Mapping: Key Decision Point (KDP) Process Guidance Document, which is accessible from the FEMA Guidelines and Standards for Flood Risk Analysis and Mapping webpage.

If levee map revisions are requested through the MT-2 Letter of Map Revision (LOMR) process, the appropriate FEMA Regional Levee Project Monitor must review the submittal so that the appropriate updates to the levee attributes and alignments can be entered in the NLD.

3.7 Levee Data Storage Standards

To depict the hazard associated with levee systems on the FIRM, FEMA collects certified data pertaining to the requirements under 44 CFR 65.10 for levee accreditation and certain scenarios pertaining to the analysis and mapping procedures for non-accredited levees. The details of the data requirements and processes are laid out in Chapter 4--Accredited Levee Systems and Chapter 6--Non-Accredited Levee Systems) of this document. Once the FEMA Levee Project Monitor or designee considers the submitted certified data, the data needs to be consistently captured and documented for search ability throughout all FEMA Regions. The methods differ depending on whether the submitted certified data for an area is associated with a FEMA-funded mapping project, an area associated with a LOMR case, or unfunded area.

3.7.1 Levee Data Storage and Documentation for the MIP

Levee accreditation data and documentation provided to mapping partners from the Region or its supporting staff, in conjunction with a PAL or analysis and mapping procedures for non-accredited levees process, needs to be captured under a funded mapping project to update the levee-related flood hazard on the FIRM. These projects can be funded solely to update the levee hazard or can be done in conjunction with a larger study effort for the flooding source, county, or watershed.

On the FEMA Mapping Information Platform (MIP), a levee purchase option is available for funded projects to capture pertinent levee information. This purchase includes several tasks available for levees, including Levee Data Capture, Analysis and Mapping Procedure for Non-Accredited Levees Data Capture, and associated QA/QC and Validation Tasks. The main tasks can be defined as follows:

- **Levee Data Capture Task**: Under this task, the assigned Project Team member or partner captures levee data certification submittals, levee analysis and mapping approach packages for non-accredited levees (i.e., Sound Reach Procedure, Freeboard Deficient Procedure Overtopping Procedure, Structural-Based Inundation Procedure, Natural Valley Procedure), new PAL offers, and Natural Valley Concurrence letters (if the full levee deficiency based analysis workflow was not applied). For FEMA-funded mapping projects, this task is intended for non-engineering modeling data only because models are to be stored separately in the Hydraulics Data Capture and/or Hydrology Data Capture Tasks in the MIP.

- **Levee Analysis and Mapping Procedures Data Capture Task**: Under this task, the assigned Project Team member or partner captures data useful to evaluate the appropriate levee analysis and mapping approach discovered during the process of Identification and Plan Preparation concluding with a full analysis and mapping procedure plan for the non-accredited levee or Natural Valley Concurrence. The team member or partner also may document the Natural Valley Concurrence under the Levee Data Capture task if the full levee analysis and mapping procedures were not funded.

All levee-related data pertaining to the mapping of the hazard and risk associated with the levee system on the FIRM should be captured under the Levee Data Capture Task. The Levee Data Capture task can be utilized to capture submitted levee data that includes levee accreditation data or data pertaining to the analysis and mapping procedure scenarios of a non-accredited levee that can be retrievable under the case number.

More detailed information on levee-related data storage is provided in, but may not be limited to, the FEMA guidance documents and technical references listed below.

The MIP User Guidance is accessible from the User Guides and Documentation page on the MSC Web Portal. Guidance Document Nos. 12, 46, 51, and 56 are accessible from the previously referenced FEMA Guidelines and Standards for Flood Risk Analysis and Mapping webpage. The Technical References are available from the previously referenced FEMA Technical References webpage.

4.0 Accredited Levee Systems

FEMA analyzes and maps the flood hazards associated with levee systems based on the information provided by other Federal agencies, levee owners, and/or communities. Accredited levee systems are depicted as reducing the base flood hazard on a Flood Insurance Rate Maps (FIRM) if FEMA has been provided with documentation and certified data that meets the

requirements of 44 CFR 65.10, including an adopted operation, maintenance and emergency preparedness plan provided by the community or other qualified entity seeking accreditation. This information can be submitted to FEMA at any time including through the Flood Risk Project study process, PAL process, or through the MT-2 process.

Accreditation can only be considered for an entire levee system which meets the full requirements of 44 CFR 65.10. As noted in Chapter 2 of this guidance, a levee system is defined as

> A flood hazard-reduction system that consists of one or more levee segments/reaches and other features such as floodwalls and pump stations, which are interconnected and necessary to ensure exclusion of the design flood from the associated hydraulically independent levee impacted area, and which are constructed and operated in accordance with sound engineering practices.

Because the levee system must be considered hydraulically independent, failure of any portion of the system will only adversely impact the system itself and not any surrounding areas or levee systems. See Figure 1.

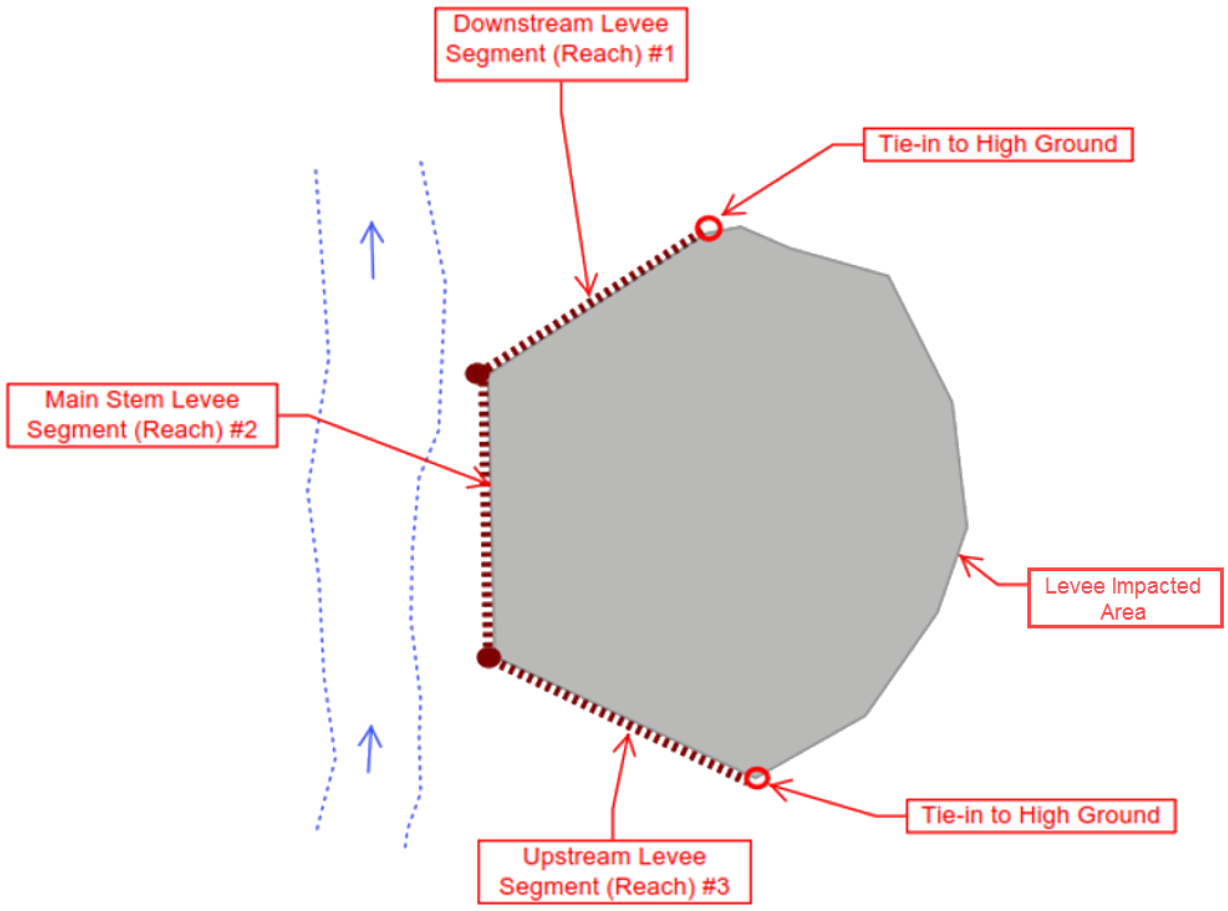

Figure 1: Example Levee System A

Levee System A is a typical example of a main stem levee with both upstream and downstream levees extending to high ground. The levee impacted area is shown in gray shading and represents the area which would be inundated during the base flood if the levee system fails to provide flood hazard reduction for the base flood. For an accredited levee system, the levee impacted area would be shown as Zone X (shaded) and labeled with the "Area with Reduced Flood Risk due to Levee" note on the Flood Insurance Rate Map.

For a levee system to be considered eligible for accreditation, the structure must first be identified as a levee system and meet the following minimum criteria:

- Meets the definitions of a levee and levee system, as defined in 44 CFR 59.1
- Has an identifiable owner
- Is operated, maintained, and inspected as a levee
- Is hydraulically independent from other levee systems or flood control structures
- Meets full requirements of 44 CFR 65.10

Unless designed as a ring levee, a levee system's requirements should also include that the levee system tie into natural high ground at either end of the system. High ground will be considered as topography that has not been revised due to manmade influences and should conform to the existing topography including no side slopes or heights outside of the typical terrain in the area. High ground should be sufficient to provide a stable foundation for the levee system to meet the structural requirements of 44 CFR 65.10 at both upstream and downstream tie-ins. For certain situations, it may not be feasible for the downstream end of a levee to tie into high ground. There may also be certain levee conditions, such as levees in urban or coastal areas where they do not tie-in to natural high ground. These situations will need to be coordinated and approved by the FEMA Regional Office and in coordination with FEMA Headquarters. Accreditation may still be considered for certain situations as described in Section 4.2 of this chapter.

4.1 44 CFR 65.10 Requirements

Regarding the NFIP, FEMA will only recognize the flood hazard and risk mapping efforts of those levee systems that meet and continue to meet the requirements of 44 CFR 65.10. Technical data submitted to meet 44 CFR 65.10(b) requirements must be certified by a registered PE. Additionally, the accreditation package must be certified by a P.E. in its entirety to ensure that all 44 CFR 65.10 elements, topographic information, as well as the hydrology and hydraulics (H&H), as updated as warranted, are consistent with the information that is basis of accrediting the levee on the FIRM. For accreditation, a levee system must meet all the requirements listed below. It should be noted that FEMA's analysis and mapping procedures for non-accredited levee systems (see Chapter 6--Non-accredited Levee Systems), necessitate that most requirements of 44 CFR 65.10 be met.

4.1.1 Freeboard

The purpose of freeboard is to acknowledge and consider the uncertainties associated with the H&H analysis and to minimize damages and threat to life and property. The freeboard requirements vary if the levee system lies within a riverine area or a coastal area. The appropriate

requirements will be determined by the modeling method used for analysis. Coastal modeling should only be considered if the available fetch of the waterbody is 0.5 miles or greater.

4.1.2 Riverine Freeboard

The riverine freeboard requirements are stated in 44 CFR 65.10(b)(1)(i) and states the following:

> *Riverine levees must provide a minimum freeboard of three feet above the water-surface level of the base flood. An additional one foot above the minimum is required within 100 feet in either side of structures (such as bridges) riverward of the levee or wherever the flow is constricted. An additional one-half foot above the minimum at the upstream end of the levee, tapering to not less than the minimum at the downstream end of the levee, is also required.*

The freeboard shall be based on the difference between the top of levee elevation to the elevation and the BFE at the riverside of the levee. A current top of levee survey or certified as-built plans should accompany any documentation regarding the freeboard requirement for a levee system. Older data may be accepted if accompanied with a statement from the certifying engineer that the older survey data still reflects current top levee conditions for the levee.

The levee shall tie into high ground at both the upstream and downstream end and maintain the required minimum freeboard at the tie into high ground. There may be cases in which high ground itself may not have the required freeboard at the tie-in location. If the tie into high ground cannot meet the minimum freeboard requirements within the vicinity of the levee, the levee can still be considered for meeting freeboard if the high ground lies above the BFE at the tie-in location of the levee. In some geographic areas, levee systems are designed to end in the absence of high ground at the downstream end. In these cases, the levee system may still be considered for accreditation as described in Subsection 4.2.1 of this guidance.

The levee freeboard should be determined based on the effective hydrologic and hydraulic models. New hydrology or hydraulics may be introduced for evaluation of freeboard as part of a FEMA initiated study, LOMR or Conditional Letter of Map Revision (CLOMR) to be evaluated by FEMA prior to consideration for accreditation. If during collection of data for accreditation it is determined that the effective BFEs are incorrect (too low), it is incumbent on the P.E. to provide updated information to FEMA through the MT-2 process such that the levee can be determined to reduce risk against the current base flood.

The tapering requirement for the additional 0.5-foot freeboard requirement at upstream end of levee system will be determined perpendicular to the flow of the base flood event and to help prevent overtopping at the structure. All aspects of levees, including mainline and tributary levees, are subject to an additional 0.5 feet of freeboard if they are perpendicular to flow at upstream end of levee. See Figure 2.

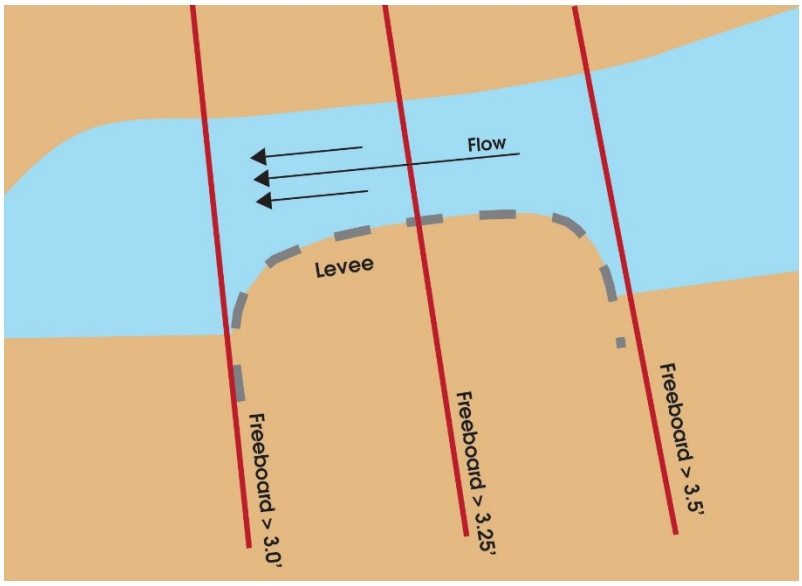

Figure 2: Freeboard Determination

There may be some circumstances in which the upstream end and downstream end of the levee are indistinguishable and the freeboard tapering requirement may not apply. This may include levees along stillwater bodies or large rivers where velocities are slow and there is no change in water-surface elevation along the length of the levee system. A waiver may be granted from FEMA for exclusion of the freeboard tapering requirement if the certifying engineer can provide data that justifies the waiver request.

The additional 1.0 foot of freeboard around structures is needed for any areas that constrict the natural flow of the river, such as bridges or culverts perpendicular to the flow. The 100 feet on either side of the structure shall be considered from the furthest upstream and downstream point of the structure that influences the flow, not the center of the structure. See Figure 3.

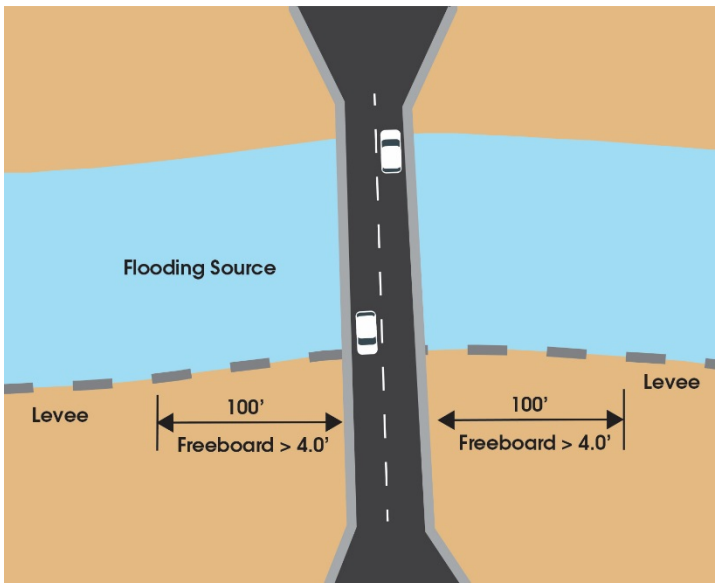

Figure 3: Freeboard Near Structures

If a structure is located at the upstream end of a levee system, the required freeboard shall be 4.0 feet (not a cumulative 4.5 feet) as the variability in flow at the upstream end of the levee and around structures has redundant uncertainties. In certain instance, it may be advantageous for the levee to have an additional half foot where debris or ice flow may incur additional flood risk or where overtopping at the structure needs to be avoided.

The additional freeboard requirement around structures may be waived if the certifying engineer can demonstrate that the structure does not influence the flow pattern of the base flood or the overtopping would not result in structure failure at that location. Possible considerations may include demonstrating the low chord of a bridge is above the base flood plus minimum freeboard requirement as well as the related embankments outside the floodplain. Debris and ice accumulation would need to be addressed before the exception is granted. In certain situations, FEMA may request additional analyses.

Freeboard must also take into account the impacts of settlement and subsidence for completeness of this section as described under 44 CFR 65.10(b)(5).

4.1.2.1 Riverine Freeboard Exceptions

Exceptions of the freeboard requirement for levees in a riverine area are stated in 44 CFR 65.10(b)(1)(ii), which states the following:

> *Occasionally, exceptions to the minimum riverine freeboard requirement described in paragraph (b)(1)(i) of this section, may be approved. Appropriate engineering analyses demonstrating adequate protection with a lesser freeboard must be submitted to support a request for such an exception. The material presented must evaluate the uncertainty in the estimate base flood elevation profile and include, but not necessarily be limited to an assessment of the statistical confidence limits of the 100-year discharge; changes in the stage-discharge relationships; and the sources, potential, and magnitude of debris, sediment, and ice accumulation. It must be also shown that the levee will remain structurally stable during the base flood when such loading considerations are imposed. Under no circumstances will freeboard of less than two feet be accepted.*

Based on the requirements laid forth in 44 CFR 65.10(b)(1)(ii), the levee must demonstrate it can meet the following items of the freeboard exception process:

- Assessment of the statistical confidence limits of the 1-percent-annual-chance discharge
- Assessment of the changes in stage discharge relationships
- Assessment of the sources, potential, and magnitude of debris, sediment, and ice accumulation
- Stability analysis indicating levee will remain structurally stable during the base flood when additional loading considerations required by the uncertainty analysis are imposed

Statistical Confidence Limits of the 1-percent-annual-chance Discharge

A statistical analysis should be performed demonstrating the conditional non-exceedance probability is 95 percent or greater for the base flood.

FEMA will accept an analysis of the upper 5-percent confidence limits of the base flood discharge or 0.2-percent-annual-chance event, whichever is greater. Additional analyses may be accepted pending FEMA concurrence.

Changes in Stage Discharge Relationships

An evaluation should be performed on the uncertainty due to changes to the stage-discharge relationship of the water body. This would include physical conditions that may change the relationship between the stage and discharge rating curve over time. It is suggested the certifying engineer utilize the appropriate USACE guidelines to demonstrate this requirement.

Sources, Potential, and Magnitude of Debris, Sediment, and Ice Accumulation

An analysis should be done demonstrating that any debris, sediment, and ice accumulation would have a negligible impact on the required freeboard.

Stability Analysis at Most Critical Section

A stability analysis should be done that conforms to the requirements laid out under 44 CFR 65.10(b)(4) demonstrating the levee will remain structurally stable with the reduced freeboard.

4.1.3 Coastal Freeboard

The coastal freeboard requirements are stated in 44 CFR 65.10(b)(1)(iii), which states the following:

> *For coastal levees, the freeboard must be established at one foot above the height of the one percent wave or the maximum wave runup (whichever is greater) associated with the 100-year stillwater surge elevation at the site.*

To show that a levee system provides base flood hazard reduction in a coastal area, the top of the levee must be equal or greater than the highest value of the following:

1. Two (2) feet above the base flood total stillwater storm surge elevation including wave setup;
2. One (1) foot above the base flood wave crest elevation; or
3. One (1) foot above the maximum base flood wave runup elevation.

The stillwater surge elevation shall be considered the water level in the absence of waves but with all other processes present. This includes the stillwater elevation of the base flood event plus a wave setup component. The wave setup is defined as the increase in mean water level above the stillwater level due to momentum transfer to the water column by waves that are breaking or otherwise dissipating their energy. Wave setup may be included in the FIS provided stillwater elevations if coupled 2D wave and surge modeling has been performed for the coastal study. If coupled 2D wave and surge modeling has not been performed wave setup may be calculated and added to the stillwater separately. Care should be taken to ensure the proper values are being used to evaluate coastal levee freeboard.

Wave runup is the vertical extent of the wave uprush on a beach or structure due to the breaking waves as shown in Figure 4.

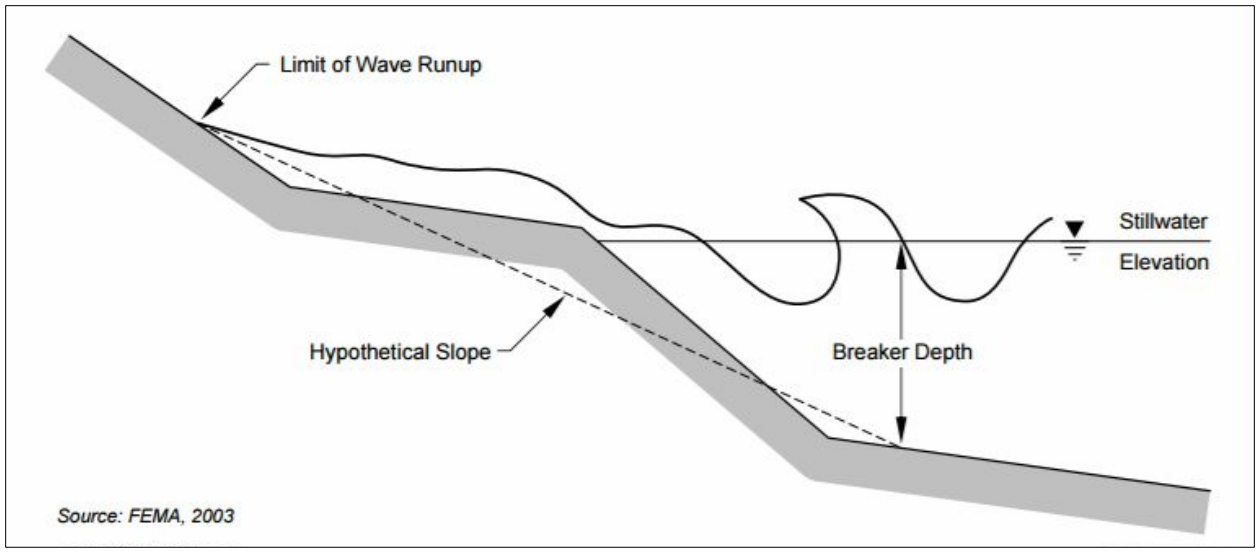

Figure 4: Wave Runup

Commonly used methods can include TAW, DIM, ACES, and CSHORE to calculate the wave runup. As stated, 44 CFR §65.10(b)(1)(iii) requires the maximum wave runup elevation. The maximum wave runup is the statistical highest wave runup attained by a group of irregular waves. The most frequently modeled wave runup heights are the mean (R_{mean} and the runup exceeded by 2 percent of the wave runup values attained by a group of irregular waves ($R_{2\%}$ Depending on the output of the method employed, one of the following conversion factors will need to be applied to calculate the maximum wave runup value required for freeboard determination:

1. $R_{max} = R_{mean} * 2.87$
2. $R_{max} = R_{2\%} * 2.87/2.23 = R_{2\%} * 1.29$

The freeboard shall be evaluated using the 1-percent total stillwater, the BFE on the FIRM, or the maximum wave runup elevation and the effective coastal model. As the 1 percent total stillwater and the maximum wave runup elevations may not be directly stated on the FIRM or in the FIS Report, these values must be derived utilizing the effective coastal modeling data. New wave runup analysis may be needed at the levee location if not including in the effective coastal study or the coastal levee is recently constructed. New coastal modeling may be introduced for evaluation of freeboard, but any new or updated models must be submitted as part of a LOMR or CLOMR to be evaluated by FEMA prior to incorporation. If the proposed model output is more conservative (BFE, velocities, duration, etc.) than the effective, the model results may be used without a LOMR or CLOMR review, pending FEMA concurrence.

4.1.3.1 Coastal Freeboard Exceptions

Exceptions to the freeboard requirement for levees in a coastal area are stated in 44 CFR 65.10(b)(1)(iv), which states the following:

> *Occasionally, exceptions to the minimum coastal levee freeboard requirement described in paragraph (b)(1)(iii) of this section, may be approved. Appropriate engineering analyses demonstrating adequate protection with a lesser freeboard must be submitted to support*

a request for such an exception. The material presented must evaluate the uncertainty in the estimated base flood loading conditions. Particular emphasis must be placed on the effects of wave attack and overtopping on the stability of the levee. Under no circumstances, however, will a freeboard of less than two feet above the 100-year stillwater surge elevation be accepted.

An analysis must be provided that evaluates the uncertainty in the base flood loading and demonstrates the stability of the levee will not be compromised with the acceptance of a lesser freeboard. Any Freeboard exceptions would need to be concurred upon by both the FEMA Region and headquarters.

4.1.4 Closures

The closures requirements are stated in 44 CFR 65.10(b)(2), which states the following: "All openings must be provided with closure devices that are structural parts of the system during operation and design according to sound engineering practice*."*

A closure shall be considered for any opening within the levee system elevated at or below the minimum freeboard elevation that pertains to a hydraulic connection between the riverside and landside of the levee system. Closures can include road openings and utility penetrations. All considered closures must have a documented and properly designed closure device and procedure in the levee system operation and maintenance manual that meets the requirements laid out for Operation Plans and Criteria under 44 CFR 65.10(c). Closures that require manual intervention, such as road openings, gate structures and manual operation for closures on pipe penetrations, must have a warning system in place that allows adequate time to respond.

Temporary closures which are not a structural part of the levee may be used as a closure device for any areas where the closure invert is above the BFE. Examples of temporary closures include sandbags, manufactured closures, and earthen closures. Temporary closures cannot be used for meeting freeboard requirements if the minimum invert elevation of the closure is below the base flood elevation.

4.1.5 Embankment Protection

The embankment protection requirements are stated in 44 CFR 65.10(b)(3), which states the following:

Engineering analyses must be submitted that demonstrate that no appreciable erosion of the levee embankment can be expected during the base flood, as a result of either currents or waves, and that anticipated erosion will not result in failure of the levee embankment or foundation directly or indirectly through the reduction of the seepage path and subsequent instability. The factors to be addressed in such analyses include but are not limited to: expected flow velocities (especially in constricted areas); expected wind and wave action; ice loading; impact of debris; slope protection techniques; duration of flooding at various stages and velocities; embankment and foundation materials; levee alignment, bends, and transitions; and levee side slopes.

Existing embankment protection must be identified along the entire levee system. It must be demonstrated that during the conditions associated with the base flood event that the duration of

the event and erosion will not compromise the stability of the levee. Flow velocities and duration of flooding used for evaluation, at a minimum, must coincide with effective hydraulic model associated with the BFE listed on the FIRM.

For coastal levees, wave runup should be addressed each time VE zones are mapped in the area or a fetch of 0.5 mile or greater is presented along the waterbody. Appropriate analyses should be presented documenting the wave impacts along the levee. If the fetch is less than 0.5 mile or circumstances are present that minimize the impacts of waves along the levee, the certifying engineer should submit a statement and documentation justifying this position.

Ice loading should be addressed when the certifying engineer believes it pertains. The certifying engineer should include a statement and justification if ice loading does not apply to the levee system.

If a previous analysis regarding the adequacy of the embankment protection is still applicable to current conditions, it may be used in lieu of providing a new analysis. A registered P.E. would need to provide the previous data and documentation and certify that it still applies to current conditions.

4.1.6 Embankment and Foundation Stability

The embankment and foundation stability requirements are stated in 44 CFR 65.10(b)(4), which states the following:

> *Engineering analyses that evaluate levee embankment stability must be submitted. The analyses provided shall evaluate expected seepage during loading conditions associated with the base flood and shall demonstrate that seepage into or through the levee foundation and embankment will not jeopardize embankment and foundation stability. An alternative analysis demonstrating that the levee is designed and constructed for stability against loading conditions for Case IV as defined by US Army Corps of Engineers (COE) manual, "Design and Construction of Levees" (EM 1110-2-1913, Chapter 6, Section II) may be used. The factors that shall be addressed in the analyses include: Depth of flooding, duration of flooding, embankment geometry and length of seepage path at critical locations, embankment and foundation materials, embankment compaction, penetrations, other design factors affecting seepage (such as drainage layers), and other design factors affecting embankment and foundation stability (such as berms).*

To meet the requirements shown above, the certifying engineer should include a seepage and stability analysis. An example method is outlined in USACE EM 1110-2-1913. This should include an examination of component material characteristics of the foundation and levee embankment, compaction design, seepage at critical locations (including at the levee tie-in locations), and penetrations. It is recommended that data including information on soil borings and laboratory results be included in the documentation for this requirement. Additionally, the impact of any structure, including but not limited to bridges and roads crossing the levee must be addressed.

If a previous seepage and stability analysis was done for the levee system, it may be used if the certifying engineer states that the findings and data are still representative of current conditions

for the levee system. A recent soil boring may be required to demonstrate the current composition of the levee is representative of the original analysis.

4.1.7 Settlement

The settlement requirements are stated in 44 CFR 65.10(b)(5), which states the following:

> *Engineering analyses must be submitted that assess the potential and magnitude of future losses of freeboard as a result of levee settlement and demonstrate that freeboard will be maintained within the minimum standards set forth in paragraph (b)(1) of this section. This analysis must address embankment loads, compressibility of embankment soils, compressibility of foundation soils, age of the levee system, and construction compaction methods. In addition, detailed settlement analysis using procedures such as those described in the COE manual, "Soil Mechanics Design – Settlement Analysis" (EM 1100-2-1904) must be submitted.*

An analysis or calculation utilizing the composition of the levee to determine current and future settlement is required for areas subject to both coastal and riverine flooding to demonstrate the current and future impacts of settlement on the freeboard. This analysis may leverage existing data if still applicable regarding calculations and composition of the levee. The analysis must address any future loss of freeboard associated with settlement over time, including subsidence impacts.

The settlement requirement is to determine the impacts on freeboard over time due to the natural settling of a levee. If a levee is not newly constructed, has not been improved and the certifying engineer can demonstrate that the minimum freeboard will be maintained when all current and future settlement is considered, a statement from the certifying engineer may suffice instead of a settlement analysis. If a levee cannot meet these requirements, a settlement analysis is still required.

4.1.8 Interior Drainage

The interior drainage requirements are stated in 44 CFR 65.10(b)(6), which states the following:

> *An analysis must be submitted that identifies the source(s) of such flooding, the extent of the flooded area, and, if the average depth is greater than one foot, the water-surface elevation(s) of the base flood. This analysis must be based on the joint probability of interior and exterior flooding and the capacity of facilities (such as drainage lines and pumps) for evacuating interior floodwaters.*

Interior drainage represents all runoff, seepage inflow, coastal overwash, and collection associated with the flooding sources tributary to the landside or interior drainage area of the levee system. An analysis must identify and demonstrate the modes and potential runoff paths from the interior drainage area. This will involve an analysis of runoff, seepage inflow, streams, coastal overwash, pump stations, detention/retention ponds, storm sewers, and other stormwater management facilities based on the judgement of the certifying engineer. The certifying engineer should evaluate and certify all data associated with the flooding sources within the interior drainage area related to handling the anticipated runoff and seepage landward of the levee and identify any ponding areas or streams. Any areas with an average depth greater than one foot

must be identified with the relevant BFE. A work map should be provided indicating the inundation areas of the analysis.

The interior drainage analysis should be done utilizing a FEMA approved hydrologic and hydraulic model. A list of these acceptable models can be found at www.fema.gov/numerical-models-meeting-minimum-requirements-national-flood-insurance-program. Any analyses done with a model that has not been accepted by FEMA will not be considered as valid under this requirement and results cannot be mapped.

The analysis should include a joint probability analysis of events on the interior and exterior of the levee, with the most conservative combination used for final analysis. In lieu of a joint probability analysis, the engineer may evaluate several scenarios rather than identify a probability-based based flood event, the most conservative combination should be used for final analysis. Comparable methodology is also available in appropriate USACE guidelines.

If a flooding source on the landside of the levee is instrumental to the interior drainage analysis but not previously identified on the FIRM, an analysis of the flooding source should be done by the certifying engineer and submitted as part of the interior drainage analysis. The analysis should meet relevant FEMA Guidance and Standards (G&S) but the associated inundation areas on the workmap provided by the certifying engineer do not need to meet FEMA G&S for mapping. However, FEMA must convert inundation areas into flood hazard areas on the FIRM, as appropriate, in accordance with FEMA G&S and in coordination with the impacted community.

If a previous analysis of interior drainage was performed and is still applicable to current hydrologic and hydraulic conditions, it may be used in lieu of providing a new analysis. A registered P.E. must certify the previous data and documentation represent current interior drainage conditions and associated flood hazards.

4.1.9 Other Design Criteria

Other design criteria are stated in 44 CFR 65.10(b)(7), which states the following:

> *In unique situations, such as those where the levee system has relatively high vulnerability, FEMA may require that other design criteria and analyses be submitted to show that the levees provide adequate protection. In such situations, sound engineering practice will be the standard on which FEMA will base its determinations. FEMA will also provide rationale for requiring this additional information.*

FEMA reserves the right to request additional information pertaining to the purpose, design, or construction, of the levee systems under unique situations that are not covered under 44 CFR 65.10(b)(1) through (6). These situations may include levees with a higher landward risk, levee systems that cannot tie into high ground and require additional analyses demonstrating that they meet and continue to meet design requirements and the structural integrity would not be compromised when exposed to the base flood event, or unique characteristics that cannot be adequately evaluated under traditional methods. FEMA will coordinate with the levee owner in writing with notification and justification for additional design requirements prior to final accreditation submission and provide adequate time for preparation of additional material.

4.1.10 Plans for Maintenance, Operation, and Emergency Preparedness

A levee submittal must include detailed plans that describe the operation, maintenance, and emergency preparedness activities to be implemented. These plans must be officially adopted and be under the jurisdiction of Federal or State agencies, an agency created by Federal or State law, or an NFIP participating community. An officially adopted plan is a plan that is signed by the Chief Executive Officer (CEO) or highest elected official of the community or the appropriate head of the agency or entity that is accepting the ultimate responsibility for all the tasks and actions listed in those plans. All plans must be prepared for the specific levee system for which accreditation is being evaluated. Generic plans that include addendums covering specific requirements may be accepted, with FEMA concurrence.

4.1.10.1 Operation Plans

The criteria for operation plans are described in 44 CFR 65.10(c), which states the following:

> *All closure devices or mechanical systems for internal drainage, whether manual or automatic, must be operated in accordance with an officially adopted operation manual, a copy of which must be provided to FEMA by the operator when levee or drainage system recognition is being sought or when the manual for a previously recognized system is revised in any manner. All operations must be under the jurisdiction of a Federal or State agency, an agency created by Federal or State law, or an agency of a community participating in the NFIP.*
>
> *(1) Closures. Operation plans for closures must include the following:*
>
> *(i) Documentation of the flood warning system, under the jurisdiction of Federal, State, or community officials, that will be used to trigger emergency operation activities and demonstration that sufficient flood warning time exists for the completed operation of all closure structures, including necessary sealing, before floodwaters reach the base of the closure.*
>
> *(ii) A formal plan of operation including specific actions and assignments of responsibility by individual name or title.*
>
> *(iii) Provisions for periodic operation, at not less than one-year intervals, of the closure structure for testing and training purposes.*
>
> *(2) Interior drainage systems. Interior drainage systems associated with levee systems usually include storage areas, gravity outlets, pumping stations, or a combination thereof. These drainage systems will be recognized by FEMA on NFIP maps for flood protection purposes only if the following minimum criteria are included in the operation plan:*
>
> *(i) Documentation of the flood warning system, under the jurisdiction of Federal, State, or community officials, that will be used to trigger emergency operation activities and demonstration that sufficient flood warning time exists to permit activation of mechanized portions of the drainage system.*

(ii) A formal plan of operation including specific actions and assignments of responsibility by individual name or title.

(iii) Provision for manual backup for the activation of automatic systems.

(iv) Provisions for periodic inspection of interior drainage systems and periodic operation of any mechanized portions for testing and training purposes. No more than one year shall elapse between either the inspections or the operations.

(3) Other operation plans and criteria. FEMA may require other operating plans and criteria to ensure that adequate protection is provided in specific situations. In such cases, sound emergency management practice will be the standard upon which FEMA determinations will be based.

All items outlined in the operation plan must reflect current conditions of the levee system and must align with the certified activities covered in 44 CFR 65.10(b)(1) through (7). All discrepancies between existing conditions or operations must be resolved prior to the levee being accepted for accreditation.

If flood fighting activities are listed in an operation plan, it must be ensured that these activities are not necessary in order to meet the requirements of 44 CFR 65.10.

If sandbags or other nonstructural measures are to be used as closure devices, the operation plan must include the details for the storage, hauling, and placement of the required materials and equipment.

Portable pumps may be accepted as modes of alleviating flood risk associated with interior drainage if details of application, flood triggers and implementation are clearly laid out in the operation plan. Portable pumps should also be shown to be readily available and onsite.

4.1.10.2 Emergency Preparedness Plans

FEMA Standard (SID) 444 requires that the submittal for levee accreditation include a current emergency preparedness plan that must, at a minimum, be adopted by the community, include the area impacted by the levee system, and procedures for emergency operations and public evacuation, meeting the requirements of 44 CFR 65.10(c)(3). Although this plan may be included in the adopted operation plan, it may also be submitted as a separate document. The size and required detail of the submitted documentation is scalable and should be appropriate for the levee system. Many communities may already be familiar with similar planning efforts and may have the relevant information available in other forms. Provided the information is appropriate to meet these requirements, the document is not required to have the title “emergency preparedness plan”. Refer to the following documents for more information on preparing these plans and sample content and format for the plans:

4.1.10.3 Maintenance Plans

The criteria for operation plans are described in 44 CFR 65.10(d), which states the following:

> *Levee systems must be maintained in accordance with an officially adopted maintenance plan, and a copy of this plan must be provided to FEMA by the owner of the levee system when recognition is being sought or when the plan for a previously recognized system is revised in any manner. All maintenance activities must be under the jurisdiction of a Federal or State agency, an agency created by Federal or State law, or an agency of a community participating in the NFIP that must assume ultimate responsibility for maintenance. This plan must document the formal procedure that ensures that the stability, height, and overall integrity of the levee and its associated structures and systems are maintained. At a minimum, maintenance plans shall specify the maintenance activities to be performed, the frequency of their performance, and the person by name or title responsible for their performance.*

The maintenance activities and the frequency of their performance to maintain the levee's compliance with requirements of 44 CFR 65.10 and well documented. At a minimum, plans must address provisions for inspection of the levee and maintenance of all mechanical systems, such as closure devices, pumps, valves, and relief wells.

4.1.11 Certification Requirements

The criteria for certification of data are described in 44 CFR 65.10(e) which states the following:

> *Data submitted to support that a given levee system complies with the structural requirements set forth in paragraphs (b)(1) through (b)(7) of this section must be certified by a registered professional engineer. Also, certified as-built plans of the levee must submitted. Certifications are subject to the definition given at §65.2 of this subchapter. In lieu of these structural requirements, a Federal agency with responsibility for levee design*

may certify that the levee has been adequately designed and constructed to provide protection against the base flood.

Certified as-built plans submitted must cover the entire levee system that is being considered for accreditation. The as-built plans should match levee features certified in design requirements under 44 CFR 65.10(b)(1) through (7). A new levee survey may be required if certified as-built plans are missing, or do not cover the entire length of the levee. The new survey must include all the necessary information for the review, including but not limited to topographic information, location and dimensions of all structures, pipes and utilities crossing the levee, and all the facilities that are part of the interior drainage system. If certified as-built plans are not available, the certifying engineer may also submit more recent plans conveying similar information if certified that they represent current conditions of the levee system.

In lieu of the structural requirements cited in 44 CFR 65.10(b)(1) through (7) a Federal agency with responsibility for levee design may certify that the levee has been adequately designed and constructed. Further details on this topic is shown under Subsection 4.2.2 (Other Federal Agency Accreditation Submittals).

4.1.11.1 Permits and Other State and Local Requirements

The submittal must adequately address all applicable Federal, State, and local laws regulations and requirements, including, but not limited to, Federal, State, and local floodplain management laws, environmental laws, and permit requirements. This requirement is the responsibility of the NFIP community. This can be verified through communication with the requester. A record of these communications must be kept in the FEMA project file for future reference.

4.2 Additional Levee Accreditation Considerations

Situations may arise during the evaluation of a levee system for accreditation that may warrant further discussion or evaluation of the specific situations. Some of the more common situations that may warrant additional considerations may include the following:

- Levees systems designed to end in the absence of high ground at the downstream end
- Considerations for review of accreditation packages from other Federal agencies
- Guidance for addressing continued accreditation of a levee system after it initially met the requirements of 44 CFR 65.10

4.2.1 Levee System Tie-In Considerations

Typically, levee systems are designed and constructed to tie into high ground at the upstream and downstream portions of the levee system, unless they are designed as ring levees. In some geographic areas, levee systems are designed to end in the absence of high ground at the downstream end. If certain criteria are still met, these levees may be eligible for accreditation. Variations of these types of levee systems are described as follows:

- The most common scenario occurs when the downstream end of a levee system meets the 44 CFR 65.10 freeboard requirements, but it does not tie into high ground at this downstream end.

- A variation occurs when the downstream end of a levee system meets the freeboard requirements but ties into a non-accredited levee (see Chapter 6) or a non-levee reach (see Chapter 7), which is part of the entire levee system. In this case, the certifying engineer must provide certified data and documentation that meets requirements of 44 CFR 65.10 to demonstrate base flood hazard reduction in the leveed impacted area.

If a levee system designed to end in the absence of high ground at the downstream end meets the requirements of 44 CFR 65.10, the "levee impacted area" defined by a natural valley analysis would be shown on a FIRM as Zone X (shaded) overlaid with the appropriate SFHAs, as determined by interior drainage analyses and/or backwater flooding that comes around the downstream end of the levee system.

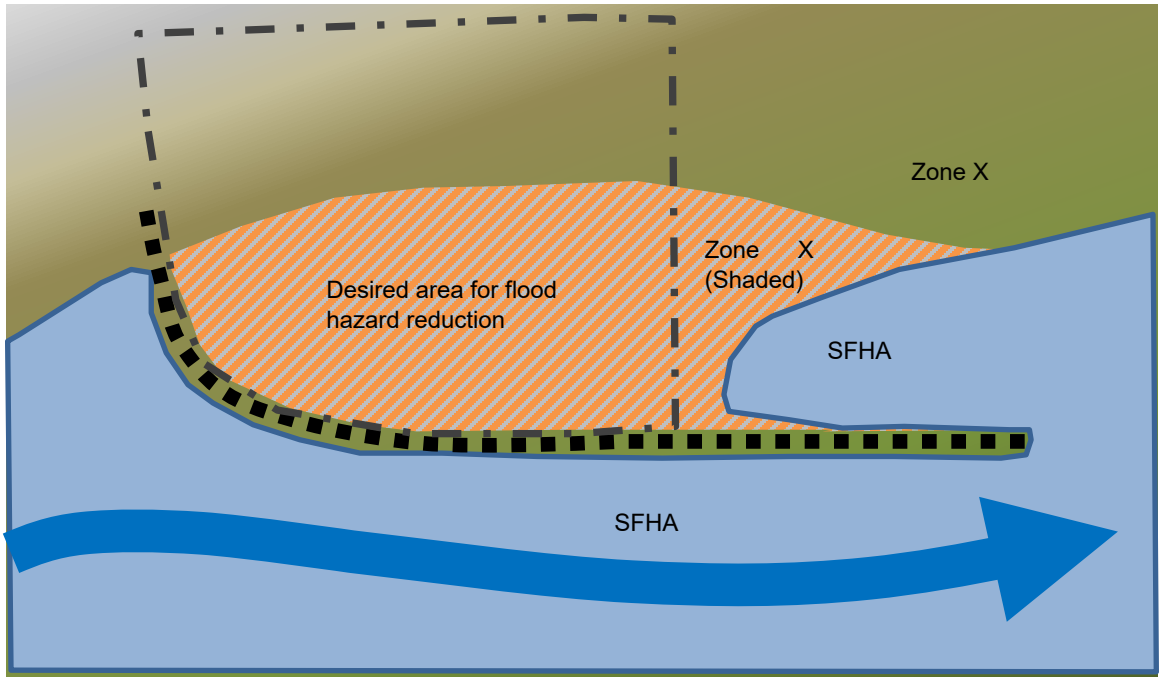

Figure 5: Levee System Designed to End in the Absence of High Ground

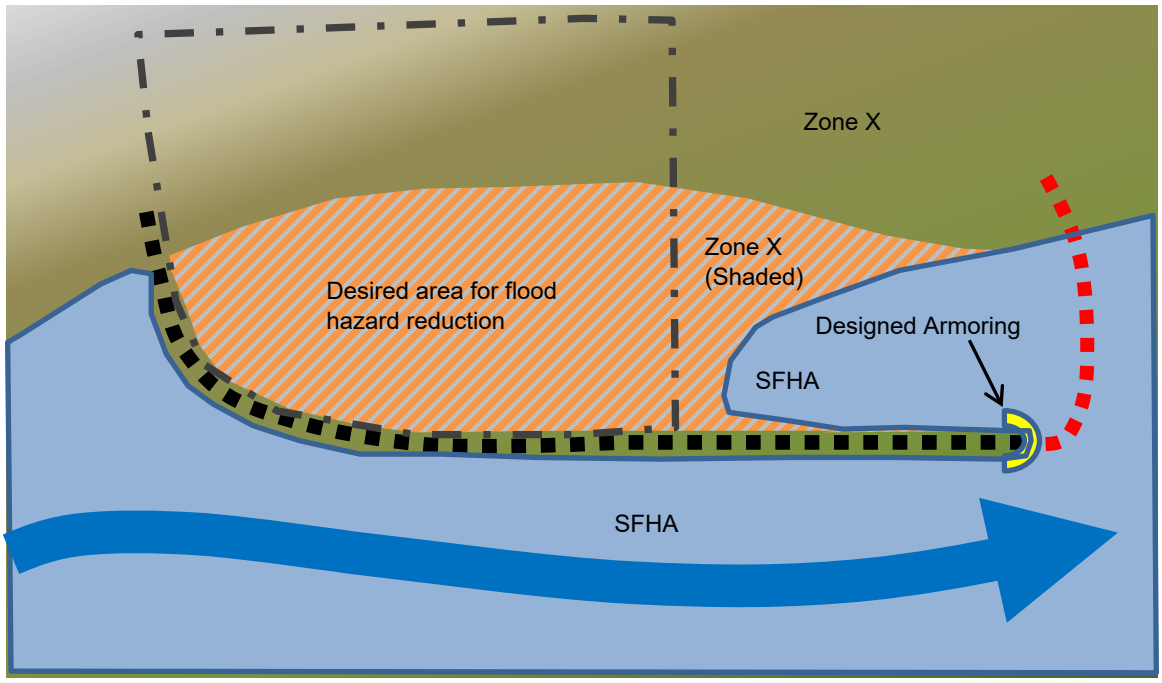

Figure 6: Levee System Tying into Non-Levee Reach

If a levee system designed to end in the absence of high ground at the downstream end does not meet the requirements of 44 CFR 65.10, but can be analyzed and mapped in accordance with the analysis and mapping procedures for non-accredited levees (See Chapter 6), the resulting flood hazard would be mapped as Zone D with the appropriate SFHA overlaid.

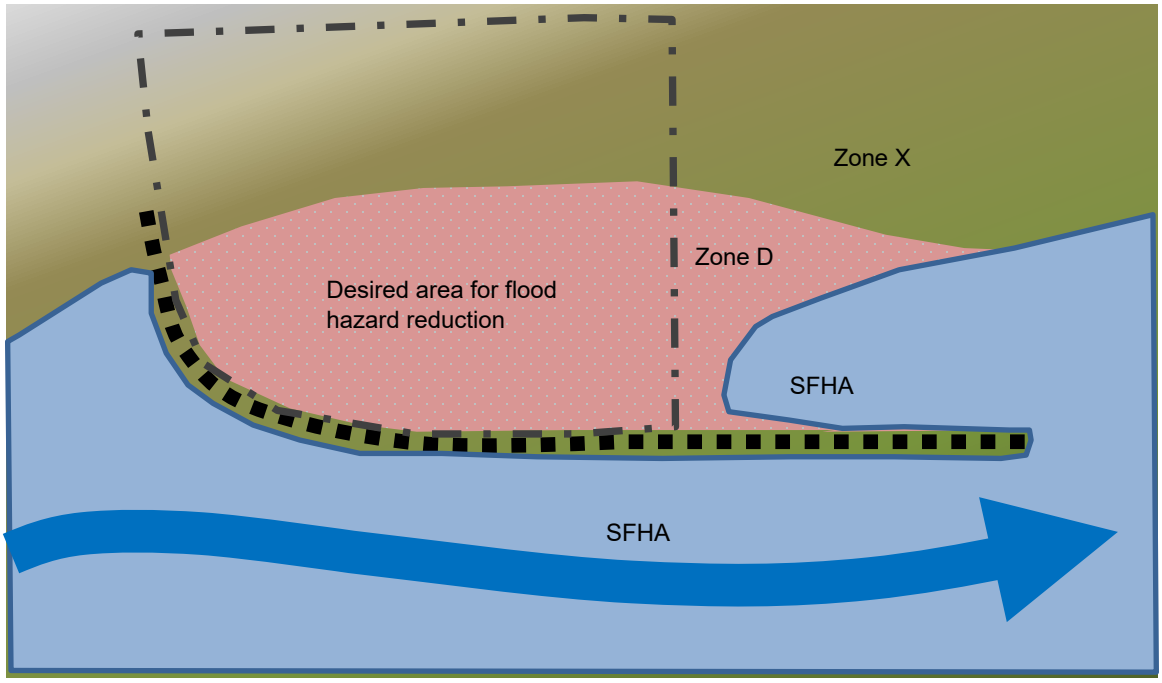

Figure 7: Non-Accredited Levee System

Before a levee system designed to end in the absence of high ground at the downstream end can be considered for accreditation or under the analysis and mapping procedures for non-accredited levees, the following three criteria must be met:

1. The levee system, including the downstream end, meets the full requirements defined in 44 CFR 65.10, except freeboard unless pursuing accreditation. But it will not be required to tie-in to high ground, which is required by 44 CFR 65.10.
2. The levee system be designed and constructed using sound engineering practices, and that the data certification specifically state that the downstream end of the levee system and the landward side exposed to any flooding conditions/loading be able to continue to meet design requirements and not "unravel" or result in the failure of the upstream levee reaches.
3. Any potential flooding that would come around the back, landward side of the downstream end of the levee be analyzed and mapped and shown on the FIRM as a SFHA.

For cases where the levee system ties into another levee or non-levee reach that has not been demonstrated to meet the requirements of 44 CFR 65.10, the certifying engineer must meet all the criteria above, as well as consider the situation where the other structure fails at the tie-in point and is analyzed with breach, overtopping, and/or natural valley analyses. The potential flooding from breaching, overtopping, or natural valley analyses on the non-accredited structure would be shown as SFHA, if this flooding creates backwater that impacts the landward side of the accredited levee system.

4.2.2 Use of Other Federal Agency Information in Support of Accreditation Submittals

There may be instances when other Federal agencies provide information to FEMA in support of a community's request for levee accreditation. The federal agency certification requirements are cited at 44 CFR 65.10(e), which states the following:

> *In lieu of these structural requirements, a Federal agency with responsibility for levee design may certify that the levee has been adequately designed and constructed to provide protection against the base flood event.*

The structural requirements are considered those listed in 44 CFR 65.10(b)(1) through (7) which are required to be certified by a registered P.E. However, if the accreditation submittal is provided by a Federal agency with responsibility for levee design, that agency may provide a recommendation for accreditation of the levee system, and FEMA may require additional supporting data and documentation, as appropriate.

In these cases, FEMA will perform a completeness check of the submitted data and documentation and may require a statement from the submitting Federal agency regarding recommendations for accreditation involving elements that do not directly align to the requirements for 44 CFR 65.10. Formally adopted operation, maintenance and emergency preparedness plans, and the most recent levee inspections are required to be submitted to FEMA for the entire levee system before FEMA will depict the levee system as accredited on a FIRM.

FEMA will review the formally adopted operation, maintenance and emergency preparedness plans to ensure that the requirements of 44 CFR 65.10(c) and (d) are met. In addition, the

community or entity seeking accreditation will be required to provide interior drainage analyses and resulting inundation maps to meet the requirements of 44 CFR 65.10(b)(6) if that information was not provided by the Federal agency.

More information on coordination with other Federal agencies as well as a list of potential agencies involved in levee design and construction can be found in Chapter 8 of this document.

4.2.2.1 Use of USACE Information in Support of Accreditation Submittals

USACE and FEMA have a long history of exchanging information related to the identification of flood hazard areas behind levees for NFIP purposes, including hydrologic and hydraulic modeling as well as detailed information regarding a specific levee system's current condition. USACE has historically provided data to FEMA in support of levee accreditation through various means including through the flood risk study, MT-2, and PAL processes, in accordance with the requirements of 44 CFR 65.10(e). USACE also provided data to FEMA in accordance with EC 1110-2-6067, USACE Process for National Flood Insurance Program (NFIP) Levee System Evaluation, which expired on August 31, 2012, and which superseded prior USACE technical letters and all other USACE policy memoranda related to evaluating levee systems with respect to FEMA accreditation under the NFIP. These evaluations provided direct findings for most of the requirements of 44 CFR 65.10. It should be noted that USACE is transitioning away from utilizing this deterministic methodology and towards a risk-informed approach for assessing levee systems with respect to accreditation for the NFIP. Refer to USACE guidance, Engineering and Construction Bulletin (ECB), No. 2019-11, Transition Guidance for Levee System Evaluations for the National Flood Insurance Program (NFIP), for USACE's current guidance on this matter: https://www.wbdg.org/ffc/dod/engineering-and-construction-bulletins-ecb.

As referenced in Section 1.3.2, Flood Protection Structure Accreditation Task Force, USACE and FEMA have an agreement in place that specifies how information collected and assessed by USACE through their agency Levee Safety Program (Program) activities [levee inspection, screening level risk assessment, Semi-Quantitative Risk Assessment (SQRA), and Quantitative Risk Assessment (QRA)] can be used to inform accreditation for NFIP purposes. The intent is to create a working partnership between FEMA, USACE, levee sponsors and communities to reduce perceived redundancies, streamline the exchange of best available information, and ensure that levee sponsors and communities receive one consistent message and are not pointed back-and-forth between the two Federal agencies. Because the coordination process between FEMA and USACE continues to evolve and improve, as mandated in multiple legislative requirements, both agencies must effectively collaborate to implement activities involving USACE Program levees. The following paragraphs describe how information from USACE levee inspections, screening level risk assessments, SQRAs, and QRAs are related to accreditation.

Levee inspections are the most frequent and familiar activity USACE performs on a levee system. Each time a USACE district conducts a levee inspection, it will identify when a levee segment meets or does not meet a specified subset of requirements in 44 CFR 65.10 as identified in the inspection checklist by providing a positive or negative finding. A positive finding is a conclusion by USACE that there is sufficient information to determine that specific criteria of 44 CFR 65.10 have been met. A negative finding is a conclusion by USACE there is sufficient information to determine that specific criteria of 44 CFR 65.10 have not been met. FEMA does not need to request additional information or documentation related to specific 44 CFR 65.10 criteria in which

USACE has provided a positive or negative finding via an inspection, unless there is additional information indicating that this finding requires verification. Other information obtained from the inspections, such as identification of serious deficiencies, may also inform a NFIP levee accreditation decision. Therefore, it is important to consider the full inspection results and not just the limited identified 44 CFR 65.10 criteria. Inspections are performed on a levee segment basis and caution should be taken to ensure that inspection results are considered collectively, in addition to the results for all the levee segments for the levee system, when using inspection information to inform a levee accreditation decision. It will also be important to consider the most recent USACE risk assessment result for a levee system. At a minimum, the USACE district will notify FEMA directly when the inspection results in a negative finding for any of the criteria. It should be noted that USACE intends to no longer assign an overall inspection rating (Acceptable, Minimally Acceptable, and Unacceptable) to levees and will begin to transition away from such ratings. FEMA will consider USACE Program levee system inspection results (and corresponding risk assessment results as necessary) and will determine if additional coordination is needed with the community and the levee sponsor for NFIP mapping purposes.

USACE screening level risk assessments are a simplified, semi-quantitative risk assessment that relies on existing data, historical performance, engineering judgment, and consequence estimation to quickly characterize the relative risks posed by levees in terms of annual exceedance probability and potential risk to life and property. All levee screenings are performed using the web-based USACE Levee Screening Tool (LST). Levee screenings are performed on each levee segment, but results are rolled up to the levee system level. Screenings provide limited information, which can inform NFIP levee accreditation decisions but do not satisfy all the requirements of 44 CFR 65.10. Each time a USACE district conducts a levee screening, it will identify when a levee segment meets or does not meet a specified subset of requirements in 44 CFR Section 65.10 as identified in the LST by providing a positive, negative, or inconclusive finding. A positive finding will be given when it is determined that based on the screening information the specified criteria of 44 CFR 65.10 has been met. Positive findings are limited to specific criteria of 44 CFR 65.10 and are insufficient to make a complete levee accreditation recommendation. Levee sponsors and communities may use positive findings to meet certain criteria of 44 CFR 65.10, but will be responsible to provide to FEMA the remaining requirements for 44 CFR 65.10 in order for FEMA to accredit the levee system on a NFIP map. A negative finding will be given when it is determined that, based on the screening information, specific criteria of 44 CFR 65.10 has not been met. Negative findings are limited to specific criteria of 44 CFR 65.10. At a minimum, the USACE district will notify FEMA directly when a screening results in a negative finding for any of the 44 CFR 65.10 criteria. An inconclusive finding will be given when it is determined that, based on the screening information, there is insufficient information to determine whether or not that specific criteria of 44 CFR 65.10 has been met.

When using screening information to inform a levee accreditation decision, caution should be taken to ensure that screenings and the corresponding inspection results are used, presented, and considered collectively, along with the results for all the levee segments for the system. FEMA will consider the USACE Program levee screening results (and corresponding inspection results) and determine if additional coordination is needed with the community and the levee sponsor for NFIP mapping purposes.

Once a levee system undergoes a full USACE semi-quantitative or quantitative risk assessment (SQRA or QRA), the NFIP findings associated with a levee screening are no longer considered valid and cannot be used to fulfill any part of 44 CFR 65.10 requirements.

When USACE performs a SQRA or QRA, it will include a recommendation related to accreditation for the NFIP based on a probabilistic determination of levee performance, if a recommendation can be made. If the results of a SQRA or QRA have a sufficient level of assurance, USACE will either recommend or not recommend that the levee system be accredited for NFIP purposes. A levee system recommendation to accredit will only be provided when all segments of the levee system, including any non-project segments (considered by FEMA as non-levee reaches; see Chapter 7 of this document), have been explicitly evaluated in the risk assessment. SQRAs may result in an accreditation recommendation, or, depending on the level of detail and degree of uncertainty, may provide an inconclusive recommendation related to accreditation for the NFIP. QRAs will have sufficient detail to make a levee accreditation recommendation each time. USACE will provide results and background information regarding QRAs and SQRAs to the FEMA Regional office in addition to a recommendation related to accreditation.

It should be noted that both the SQRA and QRA may be based on hydrologic and hydraulic modeling developed by USACE that is different from the modeling used to develop FEMA's regulatory BFEs and flood hazard mapping on the effective FIRM. As part of the SQRA and QRA, USACE evaluates the levee system performance for several flood elevations ranging from the toe to the top of the levee. When reviewing a levee accreditation recommendation provided by USACE, FEMA will compare the effective BFE (and proposed BFE, if available) to the range of flood elevations evaluated by USACE to ensure that the effective BFE (and proposed BFE, if available) falls within this range. If it does not, FEMA will need to determine if the BFE and supporting modeling in this area should be updated based on consultation with USACE. Note that USACE modeling may require additional analyses and refinements to meet FEMA's regulatory requirements, guidance, and standards for flood hazard mapping for the NFIP.

It should also be noted that USACE does not evaluate freeboard as part of a NFIP accreditation recommendation associated with SQRAs or QRAs. Thus, it is possible that the freeboard provided above the regulatory BFE may be less than the minimum freeboard requirement of 44 CFR 65.10(b)(1), and accreditation of this levee system may still be possible when based on a recommendation by USACE and supported by a SQRA or QRA. However, it is not anticipated that a recommendation for accreditation will be made when a regulatory BFE exceeds the height of the levee system since that fact would preclude FEMA from accrediting the levee system. In any case where the minimum freeboard requirement of 44 CFR 65.10(b)(1) is not met in comparison with the regulatory BFE, the FEMA Regional Office should consult with FEMA Headquarters.

Although USACE may recommend accreditation of a levee system based on a SQRA or QRA in accordance with 44 CFR 65.10(e), additional information may be required to meet the remaining requirements of 44 CFR 65.10. If USACE does not own or maintain the levee system, then the levee sponsor and/or community may be responsible for providing additional information to FEMA. These items may include, but are not limited to, interior drainage analyses, emergency preparedness plans, as-built plans, and operation and maintenance plans. FEMA will review the information provided by USACE and will determine if additional coordination is needed with the

community and the levee sponsor to obtain additional information required for NFIP mapping purposes. If a community or other entity seeks accreditation of their levee system, FEMA and USACE will work together to engage the community and levee sponsor to explain what, if any, information provided by USACE meets the requirements of 44 CFR 65.10, and what additional information the community or levee sponsor will need to provide to FEMA to meet the remaining requirements of 44 CFR 65.10.

USACE districts will coordinate with the appropriate FEMA Regions before the start of each SQRA or QRA to determine the appropriate level of engagement with FEMA. As soon as the FEMA Regional Office staff is made aware of a planned or ongoing USACE QRA or SQRA, FEMA Headquarters must be notified and engaged throughout the process to ensure documentation of lessons learned and consistent implementation of best practices. USACE will coordinate with FEMA throughout the risk assessment process, providing visibility on the data and hydrologic and hydraulic modeling being used for the risk assessment. This engagement allows FEMA to determine if potential changes to the effective base flood elevations are warranted, if and how USACE modeling may be used to update the FIRM when appropriate, and whether interior drainage is addressed in the risk assessment. It is highly recommended that USACE and FEMA jointly coordinate with the levee sponsor and community as soon as the QRA and SQRA results become available. This joint coordination will allow FEMA to communicate impacts to regulatory products and any additional items that may be the responsibility of the levee sponsor and/or community to provide to FEMA in order to meet all requirements of 44 CFR 65.10.

Ultimately, communities or parties seeking accreditation, or recognition of a levee system as reducing the base flood hazard on FIRMs, must provide data and documentation to FEMA in accordance with 44 CFR 65.10. In cases when information collected or developed by USACE through their Levee Safety Program will inform some of the requirements for levee accreditation, the communities or parties seeking accreditation may still have to provide information to fulfill the remaining requirements. It is imperative the FEMA and USACE work together to engage the levee sponsor and community to ensure that they receive one consistent message about what data is available and what is required to most appropriately analyze and map the flood hazards and to understand the flood risk in the levee-impacted area.

4.2.3 Continued Accreditation

Accreditation of a levee system requires the levee owner to demonstrate that the levee system meets, and continues to meet, the requirements of 44 CFR 65.10. Therefore, accreditation is not a one-time activity, and over time, factors may change that require FEMA to reassess accreditation status. These factors can include the expiration of the certification of data by a certifying engineer, endorsement of accreditation by a Federal agency, changes to the hydrologic or hydraulic conditions of the flooding source that necessitates a restudy, and documented deficiencies or lack of maintenance.

4.2.4 Expiration of Data Certification or Endorsement

A certifying engineer or federal agency may choose to place an expiration date on the use of the data and documentation for accreditation of a levee system. This expiration date will be tracked by FEMA in the NLD. Once the certification of this data and documentation or accreditation recommendation by a Federal agency has expired, FEMA will no longer consider the levee

system as meeting the requirements of 44 CFR 65.10. FEMA will initiate engagement with the levee owner and impacted community regarding the need to submit certified data and documentation demonstrating the levee system continues to meet the requirements of 44 CFR 65.10 to remain accredited. If this certified data and documentation cannot be provided in a timely manner, FEMA may initiate the analysis and mapping procedures for non-accredited levees (see Chapter 6) to update the flood hazard information impacted by the levee system. At no time shall a levee system with an expired certification of data be remapped as accredited without updated documentation and a certification of data by a registered P.E. or endorsement from an authorized Federal agency.

As referenced in Section 4.2.2.1, refer to USACE's transition guidance regarding expired levee system accreditation recommendations.

4.2.5 Updated Modeling along an Accredited Levee

During any update to the FIRM, the flood hazards associated with levee systems should be re-evaluated for all levee systems located along newly studied or restudied flooding sources. If the new or updated study impacts a levee system accredited in accordance with 44 CFR 65.10, the levee owner will be asked to provide data and documentation demonstrating the levee continues to meet the requirements of 44 CFR 65.10 based on the updated hydraulic loadings.

If the hydraulic loading and flood hazard information (BFE, velocities, duration, etc.) from the updated study is less than those used in the previous accreditation documentation for the requirements of 44 CFR 65.10(b), the levee may retain its accreditation status pending submission of the documents meeting the requirements of 44 CFR 65.10(c) and (d), and confirmation from the levee owner that the levee has not been structurally modified since the prior certification of data. In cases where a levee system or levee appurtenance has undergone structural modifications since the previous certification of data, submittal of data and documentation meeting the requirements of 44 CFR 65.10(b) and (e) may also be required.

If the hydraulic loading and flood hazard (BFE, velocities, duration, etc.) from the updated study is greater than those used in the previous accreditation documentation for the design requirements under 44 CFR 65.10(b), the levee owner must submit updated certified data and documentation based on the updated loading and flood hazard information demonstrating the levee system continues to meet the minimum requirements of 44 CFR 65.10. Understanding that the analysis and data collection may require additional time, Regions should take this into consideration when planning project schedules.

In some instances, an updated mapping project may include a levee system that was accredited through the LOMR process. The above requirements for updated certification of data and documentation would also apply to levees accredited through the LOMR process, granted the information provided in support of the LOMR reflects the current conditions of the levee system.

If the new or updated study impacts a levee system that has not been accredited in accordance with 44 CFR 65.10, FEMA will proceed with implementing the analysis and mapping procedures for non-accredited levees, as appropriate.

4.2.6 Noted Structural or Maintenance Deficiencies

FEMA reserves the right to re-evaluate the accreditation status of a levee system if structural or maintenance deficiencies are noted that may cause concern over the validity of the current flood hazard noted on the FIRM. This re-evaluation of the levee status on the FIRMs may be triggered based on inspection reports of State or Federal agencies or performance of the levee system in the context of a base flood event or less. If deficiencies are noted that impact requirements of 44 CFR 65.10, FEMA will coordinate with the levee owner as outlined under Chapter 6 of this document for resolution and additional data collection, as needed. If resolution is not accepted in a timely manner, FEMA will proceed with action to update the flood hazard on impacted FIRM(s) appropriately.

4.3 Levee Accreditation Reviews

This section outlines the process FEMA will follow when reviewing levee accreditation submittals. This process shall be the same for all types of submittals, including those for new and existing levee systems that have not yet been evaluated and identified during the Discovery phase, PALs, Letters of Map Change (LOMCs), Physical Map Revisions (PMRs), and accredited levee systems impacted by updated hydraulic modeling along the water body. The review process in this section applies to hydraulically independent levee systems defined in Chapter 2 of this document.

FEMA does not require communities or levee owners to accredit their levee systems, however, in accordance with NFIP regulations, communities or other parties seeking recognition of a levee system on NFIP maps may provide data and documentation demonstrating compliance with regulations cited in the 44 CFR 65.10. Once compliance with 44 CFR 65.10 is determined by FEMA, the hydraulically independent levee system will be accredited on NFIP maps, reflecting the appropriate NFIP SFHA and risk premium rate zones for levee-impacted areas. Accreditation by itself is not a guarantee or warranty of performance of levee systems during a flooding event. It is a determination that the levee system meets the minimum design, operation, and maintenance standards set forth in 44 CFR 65.10, to be shown on the NFIP map as providing flood hazard reduction from the base flood event.

The preferred format for the submittal materials is an electronic PDF with each volume clearly labeled with state, county, community, levee names and document chapter. The backup data in its native electronic format is recommended. However, FEMA may request data in PDF format in cases when data are generated using proprietary software that is not commonly used.

4.3.1 FEMA Completeness Check

The review of the levee accreditation submittal is a completeness check. It is neither a technical review nor an evaluation of design, it also is not performed to determine how a levee will perform during a flood event. The incoming data supporting 44 CFR 65.10 requirements must be certified by a registered P.E., and licensed by their respective states, or by a federal agency with responsibility for levee design. The completeness check is performed to ensure that all data demonstrating compliance with 44 CFR 65.10 is submitted, so FEMA can delineate the appropriate NFIP SFHA and risk premium rate zones on NFIP maps. However, if FEMA is presented with conflicting data, a more in-depth review can be performed. This additional and more in-depth review would require approval and consultation with FEMA Region and/or HQ, as appropriate. Although FEMA performs a completeness check for 44 CFR 65.10 compliance,

submittals must include backup data and supporting information for all calculations demonstrating the certified conclusions for each requirement. Certified summary reports without all backup data are not acceptable.

To make the levee accreditation process efficient, the reviewer may stop the review at any point if basic data requirements are not met. The examples of submittals lacking basic data includes, but not limited to, submittals with no backup data, lack of certification signatures, and submittals with data not organized intelligibly.

If the reviewer decides to stop the review, a data request should be compiled and sent to the requester noting the extent of what has already been reviewed and that additional data requests might be forthcoming once the review is restarted.

FEMA suggests that the data is submitted in the FEMA recommended data organization noted in the document titled FEMA Suggested Tabbed Submission for 44 CFR 65.10 Accreditation Material. This document allows for a cover page for each certification requirement contained in 44 CFR 65.10(b)(1) through (b6). Completeness check of the accreditation materials submitted in a format other than that presented in this document may be significantly delayed or the review may stop moving forward were the basic data appear to be missing due to poor data organization.

4.3.1.1 44 CFR 65.10 Accreditation Requirements Reviews

This portion of the completeness check is performed to verify whether the submittal has complete data to meet the minimum requirements of 44 CFR 65.10.

4.3.1.2 Freeboard Check

The data submitted must contain a profile that shows adequate freeboard exists. The reviewer shall verify the freeboard evaluation profile uses appropriate BFEs from the source consistent with sources recommended in Subsection 4.1.1 compared to the top of levee elevation. The reviewer shall request additional data in cases where the submitted data is not detailed enough to reasonably evaluate the freeboard of the levee under request for accreditation, and the submittal does not provide information about the upstream and downstream tie-ins. The evaluation criteria of upstream and downstream tie-ins shall be consistent with the requirements detailed in Subsection 4.1.2 or Subsection 4.2.1 of this document. The reviewer shall also verify freeboard information shows the levee meets all the requirements of 44 CFR 65.10(b)(1)(i), described in Section 4.1.2 of this document.

In cases where levee does not meet the minimum freeboard requirements, the reviewer shall check whether the submittal provides data supporting the levee meeting the requirements of 44 CFR 65.10(b)(1)(ii). Information on requirements for freeboard exceptions is in Subsection 4.1.2 of this document. In cases where a freeboard exception is requested, the reviewer shall verify that the levee evaluations of the other 44 CFR 65.10 criteria are evaluated using the loading conditions estimated for the freeboard exception requirements.

In case of the levees in coastal areas the reviewer shall check if the data submitted demonstrates the levee meets all the requirements of 44 CFR 65.10(b)(1)(iii), as described in Subsection 4.1.3 of this document. Occasionally, exceptions to the minimum freeboard for the levees in coastal areas are allowed. In these circumstances, the reviewer shall check the data to verify whether the

submitted data meets the requirements of 44 CFR 65.10(b)(1)(iv), described in Subsection 4.1.3 of this document and coordinate with the FEMA Regional Office and FEMA Headquarters.

4.3.1.3 Closures Check

The data submitted shall meet all the requirements outlined in Subsection 4.1.4 of this document. Closures include all levee openings and low points noted in Subsection 4.1.4 of this document. The reviewer shall check the data to verify the submittal, includes information on the numbers of closures, closure location, invert elevations, pictures, and type of closure. The reviewer shall verify consistency in the closure data between submitted reports, as-built plans, operation and maintenance plans, and emergency preparedness plans, when applicable.

The reviewer shall also verify that operations and maintenance requirements of the closures are fully met for the completeness of the closure requirements. Also, all closures must be addressed in the submitted inspection reports.

4.3.1.4 Embankment Protection Check

The data submitted shall include technical documentation regarding the existing embankment protection. The reviewer shall check the submittal documentation to verify whether the data include an analysis addressing existing protection of the levee embankment and levee foundation from erosion. The analyses shall consider all but not limited to, the factors mentioned in the Subsection 4.1.5 that might impact the erosive forces acting on the levee embankment and foundation. In cases where some of the factors are not accounted for (such as wave action, ice loading, etc.), the reviewer shall seek a written justification for the omission from the certifying engineer. Analysis must at minimum use loadings associated with the effective base flood event.

The reviewer shall check the submittal to verify the type of current embankment protection for the entire levee system, references to accepted documents to demonstrate current protection is adequate against the erosive forces acting on the levee embankment and foundation during the base flood, and backup data supporting the analysis is provided.

USACE has developed reference materials for embankment protection evaluations that may be used as technical reference. Other Federal agencies, such as the U.S. Bureau of Reclamation (USBR), may have technical references that may be leveraged. It is up to the certifying engineer to identify and use the methodology that is most appropriate for the levee being evaluated, other evaluation approaches deemed applicable by the certifying engineer may also be considered if warranted and approved.

4.3.1.5 Embankment and Foundation Stability Check

The data submitted shall include technical documentation addressing the embankment and foundation stability of the levee. The reviewer shall check the submitted documentation to verify whether the submitted data includes a seepage and stability analyses demonstrating the levee and foundation stability during the base flood or less frequent events. In cases where flood control structures are flood walls the reviewer shall also check the analyses demonstrating adequate strength and stability of flood walls are also provided. The analyses shall at the minimum consider the stability conditions mentioned in the Subsection 4.1.6 that might impact the stability of the flood control structures and their foundation.

The reviewer shall check the submittal to verify the submittal identifies the location of evaluated flood control structure section, and that justification is provided for its selection. The reviewer shall also check submittal to verify it includes the backup data supporting the analysis.

The reviewer shall also review the submitted documentation to verify loading conditions used in the analysis are consistent with the base flood used to evaluate other requirements of 44 CFR 65.10.

USACE has developed reference material for levee and foundation stability evaluations that may be used as technical reference. It is up to the certifying engineer to identify and use the methodology that is most appropriate for the levee being evaluated, other methodologies to evaluate levee and foundation stability deemed applicable by the certifying engineer may also be considered if warranted and approved.

4.3.1.6 Settlement Check

The data submitted shall include technical documentation that assesses the potential settlement of the levee and reduced freeboard over time. The reviewer shall check the submitted data to verify it includes settlement analysis, information on the current top of levee elevations, and subsidence evaluation, where applicable. The reviewer shall check that the submitted documentation has information to demonstrate that freeboard will be maintained within the minimum standards for the entire levee system after settlement and applicable subsidence are considered. The minimum freeboard applied for evaluation shall correspond to the requirements established in Subsection 4.1.7.

The reviewer shall check the submittal report to verify the analysis considers all, but not limited to, the factors mentioned in Subsection 4.1.7, that might impact the settlement and future freeboard of the levee. In cases where some of the factors are not considered, the reviewer shall request written justification from certifying engineer for omission. The reviewer shall check the submitted data to verify the backup data supporting the analysis is included.

USACE has developed reference material for settlement evaluations that may be used as technical reference. Other Federal agencies, such as USBR, may have technical references that may be leveraged. It is up to the certifying engineer to identify and use the methodology that is most appropriate for the levee being evaluated. Other approaches to evaluate a levee's settlement and estimating future loss of freeboard deemed applicable by the certifying engineer may also be considered if warranted and approved.

4.3.1.7 Interior Drainage Check

The reviewer shall verify the submittal includes a hydrologic and hydraulic analysis of the flooding sources on the landside of the levee, identifies the source(s) and extent of flooding due to the flooding sources on the landside, includes a topographic work map showing the extent of any flooded area, and in cases where the average depth of flooding is greater than one-foot, the water-surface elevation of the base flood. New BFEs and/or SFHAs resulting from the interior drainage analysis are subject to the appeal process set forth in 44 CFR Part 67.

The reviewer shall verify the analyses submitted are performed based on the joint probability of interior and exterior flooding, and the capacity and operation of the facilities to evacuate interior

floodwaters in the analysis is consistent to the operation and maintenance plans submitted for the levee system.

USACE has developed reference material for joint probability analysis that is commonly used as technical reference for interior drainage analysis. However, analyses performed using other relevant agency or local jurisdiction publications on joint probability are also accepted. The reviewer shall verify the methodology used for interior drainage analysis comply with the methods discussed in Subsection 4.1.8.

The reviewer shall perform a thorough H&H review for all flooding sources identified within the impacted drainage area. The review of the interior drainage analysis shall involve evaluation of the submitted data to check the methodology used complies with the requirements of 44 CFR 65.10 detailed in Subsection 4.1.8 of this document, as well as meets current FEMA G&S for H&H analyses. The reviewer shall check the data submitted to verify the digital versions of the models used as well as any background calculations or references are included.

4.3.1.8 Other Design Criteria Check

In unique situations FEMA may require that additional design criteria and analysis be submitted. The reviewer shall coordinate with FEMA to verify such additional design criteria is applicable for the levee under evaluation. When additional design criteria are applicable, the reviewer shall verify the analysis and design addressing the additional design criteria requested by FEMA and the backup data is provided.

4.3.1.9 Operation Plans and Criteria Check

The reviewer shall verify that the submittal includes an officially adopted operation plan that includes information on interior drainage systems, if any, and all closure structures or devices. The reviewer shall check the submitted package includes official adoption documentations the plan meets all the requirements of 44 CFR 65.10(c) as described in Subsection 4.1.10, and it corresponds with the other sections of the submittal and backup data.

4.3.1.10 Emergency Preparedness Plan Check

The levee accreditation submittal shall also include an emergency preparedness plan. The plan must comply with all the emergency preparedness plan requirements discussed in Subsection 4.1.10. Some of the commonly used emergency preparedness plan guideline documents are also provided in this subsection.

The reviewer shall verify the submittal include an officially adopted emergency preparedness plan and it meets the minimum requirements discussed in Subsection 4.1.10. In cases where emergency preparedness plan is a part of the levee's operation plan a separate official adoption document is not necessary.

4.3.1.11 Maintenance Plans Check

The reviewer shall verify the submittal includes an officially adopted maintenance plan, verify the plan documents the formal procedure that addresses all the requirements of 44 CFR 65.10(d) as described in Subsection 4.1.10, and the plan corresponds to other sections of the submittal and backup data.

The reviewer shall also verify that both the operation and maintenance plans are prepared for the specific levee for which accreditation is requested. In cases where generic O&M plans, non-specific to the levee system, i.e., plans that cover an entire county or State is used, they are only used as reference and the submitted operation and maintenance plan also include operational and maintenance procedure specific to the levee requested for accreditation.

4.3.1.12 Certification Requirements Check

The reviewer shall verify the data submitted, associated with the requirements of 44 CFR 65.10(b)(1) through (7), are certified by a registered PE, licensed by the appropriate State. If the data are submitted by a Federal agency with responsibility for levee design, the reviewer shall confirm that documentation consistent with Subsection 4.2.2 is provided.

The reviewer shall also check the submitted data to verify a certified copy of as-built plans are submitted and they correspond with other submitted data.

When as-built plans from levee's original construction drawings are used, the as-builts generally are updated adding notes and updates at the locations where the leveraged data does not correctly represent the current condition. It is the certifying engineer's responsibility to ensure the submitted data are still valid. The reviewer shall verify the submittal package in its entirety is certified by a PE.

Once the completeness check is finished and all required components have been submitted and deemed complete, FEMA will accredit the corresponding levee on the affected NFIP map(s). If any component is found to be missing or erroneous and the requester cannot provide missing data to show compliance with 44 CFR 65.10, FEMA will not accredit the levee and reserves the right to suspend or deny the request.

4.3.1.13 Other Checks

This portion of the checks are performed to verify the submitted data complies with other regulatory and FEMA standards.

4.3.1.14 Regulations

The reviewer shall verify the requester has confirmed that the all the applicable permits related to the levee have been obtained. The permits include but, are not limited to the regulations mentioned in Subsection 4.1.11. The verification is generally through communication with the requester. A record of these communications shall be kept in a file. In cases where the requestor provides the information, the data submitted shall be organized and kept in a file.

4.3.1.15 New Hydrologic and Hydraulic Analyses

If new hydrologic and/or hydraulic analyses are submitted as part of a levee certification package, the submittal must follow the process outlined in Subsection 4.4.1.

4.3.1.16 Inspection Reports

The reviewer shall verify the documentation, including tests and inspection reports that are required by regulation under 44 CFR 65.10(c)(1)(iii) and 65.10(c)(2)(iv), are provided.

All other applicable inspection reports from either USACE or other sources must be considered as part of the review to ensure that any issues related to 44 CFR 65.10 have been addressed. The reviewer shall verify these documents are provided in the submittal.

4.3.1.17 Levee System Cross Reference Check and Certified Reach Documentation

The reviewer shall verify that all components in 44 CFR 65.10 use the same flooding elevations and conditions, and that the entire levee system (if a system consists of different reaches) is considered in the submittal. In cases where the levee system provides flood hazard reduction from multiple flooding sources, the reviewer shall verify the certified analyses use flood elevations from the appropriate flooding source(s).

A certifying engineer may submit certified data and documentation for a levee reach that may not meet all components in 44 CFR 65.10 under the analysis and mapping procedure for non-accredited levee systems (see Chapter 6). In these instances, the submittal may not include data for the entire levee system. In these cases, the submitted package shall clearly identify the reach for which the data is applicable. The package shall also include all the necessary data to demonstrate the section under evaluation meets the definition of a levee reach. The reviewer shall perform the completeness check of the data, document the applicable procedure consistent with the analysis and mapping procedure for non-accredited levees, and clearly identify the levee reach for which the data is submitted. The reviewer shall inform FEMA and the requester that the data does not meet requirements for the full accreditation of the levee system.

4.3.2 Data Storage and Delivery

Once the accreditation package has been considered complete by FEMA or its designee, the applicable correspondence, complete accreditation package, and all applicable models will be provided to the mapping partner responsible for updating the FIRM with revised flood hazard information. Data will be captured under the applicable funded project and MIP case number as described in the Guidance Document No. 51, Data Capture – Workflow Details, and the Data Capture Technical Reference.

Complete levee accreditation packages that do not have a funded mapping project or accreditation data submitted through the MT-2 process will be captured and stored as laid out under Section 3.6 of this document.

4.4 Accredited Levee Mapping and Notes

4.4.1 New Hydrologic and Hydraulic Analysis

If a new hydrologic and/or hydraulic analysis for the exterior flooding source is submitted as part of a levee accreditation package, the package must be reviewed to determine that it meets FEMA criteria before it can be used to revise the effective BFEs. If the new hydrologic and/or hydraulic analysis indicates the base flood hazards are less conservative than the effective flood hazards, this review must occur and the effective BFEs must be updated before the levee can be accredited. However, if the new hydrologic and/or hydraulic analysis indicate the base flood hazards are more conservative than the effective flood hazards, the levee system may be accredited without revising the BFEs; FEMA will determine if a future revision based on the new analysis is warranted.

4.4.2 "With Levee" and Natural Valley Analyses

If a new hydrologic and/or hydraulic analysis is performed in an area with a levee, then both "with levee" and "natural valley" analyses must be performed. For accredited levees, the "with levee" analysis contains all of the 1-percent-annual-chance discharge riverward of the levee. The "natural valley" procedure assumes the levee does not impede floodflows. Because the "natural valley" analysis allows for additional conveyance and/or storage of floodwaters on the landward side of the levee, it typically results in lower BFEs than the "with levee" analysis.

If levees have been built on both sides of the flooding source, the "with levee" analysis assumes that the base flood discharge is contained between the two levees. However, a separate "natural valley" analysis is required for each levee. The "natural valley" analysis for the right levee should assume the left levee is in place and the "natural valley" analysis for the left levee should assume that the right levee is in place. This approach should also be used for analyzing the 0.2-percent-annual-chance flood or lesser events if requested.

Both the "with levee" and "natural valley" analyses should include all of the effective FIS flood frequency profiles and those flood frequency profiles required by current FEMA guidance to be analyzed for the project.

4.4.3 Flood Profiles

For accredited levees, the results of the "with levee" hydraulic analysis will be used to generate the Flood Profiles for the FIS Report. It is not necessary to generate Flood Profiles for the "natural valley" analysis unless specifically requested by the community and approved by FEMA.

4.4.4 BFE and SFHA Mapping

For accredited levees, the results of the "with levee" hydraulic analysis are used to map the BFEs riverward of the levee. The area landward of the levee centerline will be mapped using water-surface elevations from the "natural valley" hydraulic analysis and will be mapped on the best available topography landward of the levee. The BFEs will be mapped landward of the levee as Zone X (shaded) to show the area with a reduced base flood hazard. The 0.2-percent-annual-chance flood will also be mapped landward of the levee as Zone X (shaded). These two areas of Zone X (shaded) will be differentiated by using the appropriate symbology and notes as described in the FIRM Panel Technical Reference. Any areas of residual risk and interior drainage flooding that fall within this area will be mapped as an SFHA, the area subject to inundation from the base flood.

4.4.5 Floodway Analysis and Mapping Methods

NFIP regulations and Standards SID 69 and 70 state:

> Floodway surcharge values must be less than or equal to 1.0 foot. If the state (or other jurisdiction) has established more stringent regulations, these regulations take precedence over the NFIP regulatory standard. Further reduction of maximum allowable surcharge limits can be used if required or requested and approved by the communities impacted… [and] If a stream forms the boundary between two or more states and/or tribes, either the 1.0-foot maximum allowable rise criterion or existing floodway agreements between the parties shall be used.

Coordination with communities may be necessary in establishing the floodway extents implementing the floodway analysis methodology described below. The community coordination process shall be in accordance to Section 2 of FEMA Guidance Document No. 79, Floodway Analysis and Mapping, accessible through the FEMA Flood Risk Analysis and Mapping webpage.

Accredited levee systems are assumed to be hydraulically significant levees, and floodways for areas impacted by accredited levee systems should be computed using the same procedures outlined in Chapter 6 of this document for hydraulically significant levees. Please refer to Section 6.19 of this document for a description of these methods.

4.4.6 Multiple Levee Scenarios

When multiple levee systems may reduce flood hazards for the same area, each system must be individually analyzed, and the higher BFEs from the "natural valley" analyses shall be used on the FIRM for the levee-impacted area. If an area is impacted by both an accredited levee and non-accredited levee systems, the area shall be mapped in accordance with the appropriate procedure for both the accredited and non-accredited levee systems. Refer to the Chapter 6 of this document for information about mapping non-accredited levees.

In some cases, where one or more levee systems are located within the levee-impacted area of a larger levee system (exterior levee system), such as interior drainage levees (interior levee system). In these cases, it may be possible that both levee systems are accredited (see Figure 8) and the natural valley floodplain for the interior levee will fall within the natural valley floodplain for the exterior levee. For mapping purposes, gutterlines should be used to separate the Zone X (shaded) areas impacted by the interior levees from the Zone X (shaded) area impacted by only the exterior levee system.

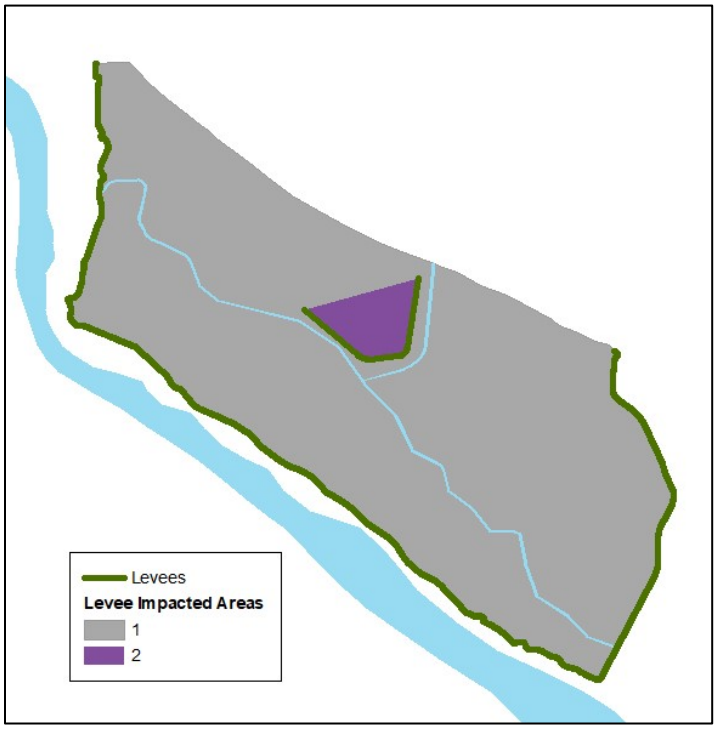

Figure 8: Multiple-Levee Scenario

In many cases, the interior levee system is designed to provide flood hazard reductions from an interior flooding source that may have an identified SFHA with a lower flood hazard than the exterior levee system. Three basic scenarios are possible:

1. If the exterior levee system is accredited (levee-impacted area 1 in Figure 8), the accreditation of any interior levee systems (levee-impacted area 2 in Figure 8) shall be based on the characteristics of the interior flooding sources to be shown with a reduced flood hazard.
2. If the exterior levee system is non-accredited (levee-impacted area 1 in Figure 8), the accreditation of any interior levee system (levee-impacted area 2 in Figure 8) shall be based on the characteristics of both the interior flooding sources and the exterior flooding sources to be shown with a reduced flood hazard.
3. If the interior levee system does not meet the accreditation requirements in either case, it shall be mapped using the procedures for non-accredited levee systems.

When no SFHA has been identified from any flooding source or interior drainage system associated with an interior levee, then an analysis of flood hazards shall be performed per Section 6.10 of this document to determine if a flood hazard exists.

4.4.7 Accredited Levee Notes to Users

When an accredited levee is shown on a FIRM panel, the Notes to Users section of the panel should include an accredited levee note as described in the FIRM Panel Technical Reference. This note should also be included in the Notes to Users section of the FIS Report.

4.4.8 Accredited Levees in the FIS Report

All accredited levees should be referenced in the FIS Report as explained in the FIS Report Technical Reference. This consists of including all levees in Table 9 of the FIS Report and referencing them on the Floodway Data Table as appropriate.

5.0 Provisionally Accredited Levee Systems

5.1 Provisional Levee Accreditation Overview

Levee owners and other levee stakeholders are responsible for providing 44 CFR 65.10-compliant design, operation, and maintenance documentation for FEMA to issue FIRMs recognizing the base flood hazard reduction capability of levee systems, also referred to as accreditation. In 2005, FEMA issued guidelines to clarify roles and responsibilities for levee flood hazard identification during a Flood Risk Project. FEMA further recognized that levee-impacted communities or other levee stakeholders may not have all documentation readily available to meet the requirements of 44 CFR 65.10, which could delay a Flood Risk Project. In 2007, FEMA issued guidelines establishing the PAL designation. The PAL designation provides communities and levee owners a specified timeframe to gather and submit 44 CFR 65.10-compliant data and documentation while allowing FEMA to move forward with preliminary and effective FIRMs while minimizing impact to the map production schedule.

A levee system is not eligible for a PAL designation if it is not shown as providing flood hazard reduction on the effective FIRM or on an attachment to a LOMR. A PAL designation can only be offered once for any given levee system.

This chapter provides guidance on determining if a levee system is eligible for a PAL designation and, if so, the process to offer the PAL, associated communication, and mapping. The determination of PAL eligibility requires coordination with Federal, State, and local levee stakeholders to support the decision-making process. Table 2 highlights the eligibility requirements that a levee system must meet to be considered for a PAL designation and provides the appropriate PAL category for the offer to the levee owner. If the levee system cannot meet any of the eligibility requirements listed in Table 2, then the levee system is not eligible for a PAL designation.

Table 2: Summary of Minimum PAL Requirements

Non-USACE or USACE Program Levee System	PAL Category	Levee System Shown as Providing Base Flood Hazard Reduction on Effective FIRM	PAL Not Previously Offered for Levee System
Non-USACE Program Levee System	A	X	X
USACE Program Levee System	B	X	X

5.2 PAL Eligibility Requirements

When levee systems are identified during a Flood Risk Project, a PAL designation may be considered in certain circumstances. Upon completing the levee system identification process, as specified in Section 3.3 of this document, within the project area, a Project Team member will perform an assessment of PAL eligibility. For a PAL eligibility determination, the levee systems identified should first be separated into three categories:

1. Levee systems not identified on the effective FIRM
2. Levee systems identified on the effective FIRM, but not shown as providing base flood hazard reduction
3. Levee systems identified on the effective FIRM and are shown as providing base flood hazard reduction

Only levee systems identified on the effective FIRM and shown as providing base flood hazard reduction can be considered for a PAL designation. If the levee system is shown as providing base flood hazard reduction on the effective FIRM, the Project Team must determine whether a PAL designation has been previously offered for the levee system. FEMA will only offer a PAL designation once to any given levee system. If a PAL designation was previously offered for the levee system, then the levee system is not PAL eligible.

To determine if a levee system is “PAL eligible”, FEMA must first establish, through coordination with USACE, whether the levee system is a USACE Program levee system or a non-USACE Program levee system.

For this document, USACE Program levee systems typically have recent inspection and risk assessment data, and are described in the following categories:

- Levee systems built by USACE that were authorized for construction by the U.S. Congress or by USACE continuing authorities (e.g., Section 205). These levee systems may contain levee projects constructed by non-Federal entities or other Federal agencies and incorporated into the USACE Program levee system by specific congressional action. In either case, these levee systems may be:
    - Owned or partially owned by USACE
    - Operated and maintained by USACE
    - Operated and maintained by a local sponsor (also referred to levee sponsor, public sponsor, or non-federal sponsor)
    - A combination of the above
- Non-Federal projects that are Active in the USACE Rehabilitation Program (pursuant to PL 84-99).

For non-federal projects that are Inactive in the USACE Rehabilitation Program, but were previously Active, USACE may still have data available to share with FEMA. As USACE continues to collect and expand information for all levees in the Nation in the NLD, it is best practice to look for information in the NLD and coordinate with USACE.

For this document, levee systems that do not meet the above criteria for a USACE Program levee system will be considered a non-USACE Program levee system, and this includes non-federal projects made Inactive in the USACE Rehabilitation Program.

Additionally, levee system symbology on the effective FIRM is important when determining PAL eligibility. If levee system symbology is not shown on the effective FIRM, the Project Team will consider the presence of a levee and the purpose of the structure. If levee symbology is not identified on an effective FIRM, but the structure implies base flood hazard reduction and has been verified to meet the definition of a levee system, a PAL designation may be considered.

Consideration of offering a PAL designation for a USACE Program levee system or a non-USACE Program levee system can follow different procedures and require different documentation, and as a result, have different PAL categories. The PAL categories are A: non-USACE Program levee system and B: USACE Program levee system. Table 2 shows that both categories of levee systems must meet the same general PAL eligibility requirements. Figure 9 (on page 61 of this document) provides a workflow process for assessment of PAL eligibility.

5.3 Considerations for Offering PAL to PAL Eligible Levee Systems

Even when a levee system is eligible for PAL Category A or B, FEMA may find that offering a PAL designation is not the best course of action. Therefore, additional considerations should be assessed before a PAL designation is offered.

If a levee system is determined to be PAL eligible per Section 5.2, the next step is for the Project Team to consider if:

- The levee system crest is at least 2 feet above the effective BFE.

- Operation and maintenance requirements of 44 CFR 65.10(c) and 44 CFR 65.10(d) have been met.

O&M plans under the jurisdiction of a federal or state agency, an agency created by federal or state law, or agency of a community participating in the NFIP is a regulatory requirement of 44 CFR 65.10(c) and 44 CFR 65.10(d). It is also information all communities are required to provide as part of a qualifying levee system for a PAL designation. FEMA will evaluate, before offering a PAL designation, whether an O&M plan under one of the jurisdictions cited above is available for the levee system. If the levee system does not have an O&M plan per 44 CFR 65.10(c) and 44 CFR 65.10(d), FEMA may not offer a PAL designation for the levee system.

Considerations and coordination with levee system stakeholders vary somewhat between non-USACE Program levee systems and USACE Program levee systems when deciding to offer a PAL designation and are described in detail in Subsections 5.3.1 and 5.3.2 and illustrated in the decision tree in Figure 9 on page 61 of this document.

5.3.1 PAL Category A – Considerations for Offering PAL for Non-USACE Program Levee Systems

The Project Team will assess the following considerations for offering a PAL designation when a levee system is determined to be eligible for PAL Category A:

- Where the levee system crest elevation and BFE are available, the Project Team should compare them to determine if the levee system crest elevation is at least 2 feet above the effective BFE. At no point along the levee system should the crest elevation be less than 2 feet above the effective BFE.
- Does information exist that indicates the levee system does not meet the design criteria of 65.10(b)?
- The levee owner must demonstrate that the levee system meets the operation and maintenance requirements of 44 CFR 65.10(c) and 44 CFR 65.10(d). The levee owner must be able to provide records of levee system maintenance and operation, as well as tests of mechanized interior drainage systems, if applicable.

Even for a non-USACE Program levee system, FEMA should first coordinate with USACE to determine if they have any data related to the levee system. The assessment to offer a PAL designation for non-USACE Program levee systems should then be performed in coordination with the local levee owner or the entity responsible for the levee system operation and maintenance.

It may be more difficult to obtain levee system crest elevation data for non-USACE Program levee systems. FEMA will need to work with the levee owner(s) to determine best available levee system crest elevation information and BFE information. FEMA will estimate the BFE(s). New or more up to date modeling may result in BFEs that are different than what is provided in the effective study. New or more recent BFEs may be used only if increases are demonstrated above the effective BFEs information. Water-surface elevation decreases in new or updated locations may not be used in place of the effective information.

FEMA recognizes that non-USACE Program levee systems may not have levee inspections and/or levee risk assessments like a USACE Program levee system may have. At a minimum, the levee owner must be able to provide records of levee system operation and maintenance, as well as tests of mechanized interior drainage systems, if applicable. If no operation and maintenance records exist, FEMA will not offer a PAL designation for the levee system.

5.3.2 PAL Category B – Considerations for Offering PAL to USACE Program Levee Systems

This subsection provides considerations that the Project Team should be assess before FEMA will offer a PAL designation to USACE Program levee systems determined to be eligible for PAL Category B. In addition, this subsection identifies the suggested coordination with USACE when assessing whether a PAL should be offered. FEMA and USACE will initially coordinate PAL assessment and then should jointly engage the local levee system sponsor and impacted communities after it has been agreed that the levee system is PAL eligible. Coordination with USACE will include requesting data and documentation concerning USACE Program levee systems to facilitate the assessment for offering a PAL designation.

The Project Team should assess the following considerations for offering a PAL designation when a levee system is determined to be eligible for PAL Category B:

- No readily available information indicates that the levee system does not have base flood risk reduction capability.
- Where the levee system crest elevation and BFE are available, the Project Team should compare them to determine if the levee system crest elevation is at least 2 feet above BFE. At no point along the levee system, can the crest elevation be less than 2 feet above BFE.
- Does information exist that indicates the levee system does not meet the design criteria of 44 CFR 65.10(b)?
- The levee owner must demonstrate that the levee system meets the operation and maintenance requirements of 44 CFR 65.10(c) and 44 CFR 65.10(d).
- For USACE Program levee systems, levee inspections and risk assessments provide valuable information to help determine if the above-mentioned criteria may be met for the levee system.

In some cases, new or more up to date modeling may result in BFEs that are different than what is provided in the effective study. New or more recent BFEs may be used only if increases are demonstrated above the effective BFEs information. Water-surface elevation decreases in new or updated locations may not be used in place of the effective information.

For non-Federal levee systems that have been placed on Inactive status in the USACE Rehabilitation Program, the FEMA Regional Office will obtain a copy of the USACE notification letter to the levee owner informing the owner that the levee system status has been changed from Active to Inactive. They will also coordinate with the appropriate USACE District office to determine whether the levee owner should be offered a PAL designation for the levee system.

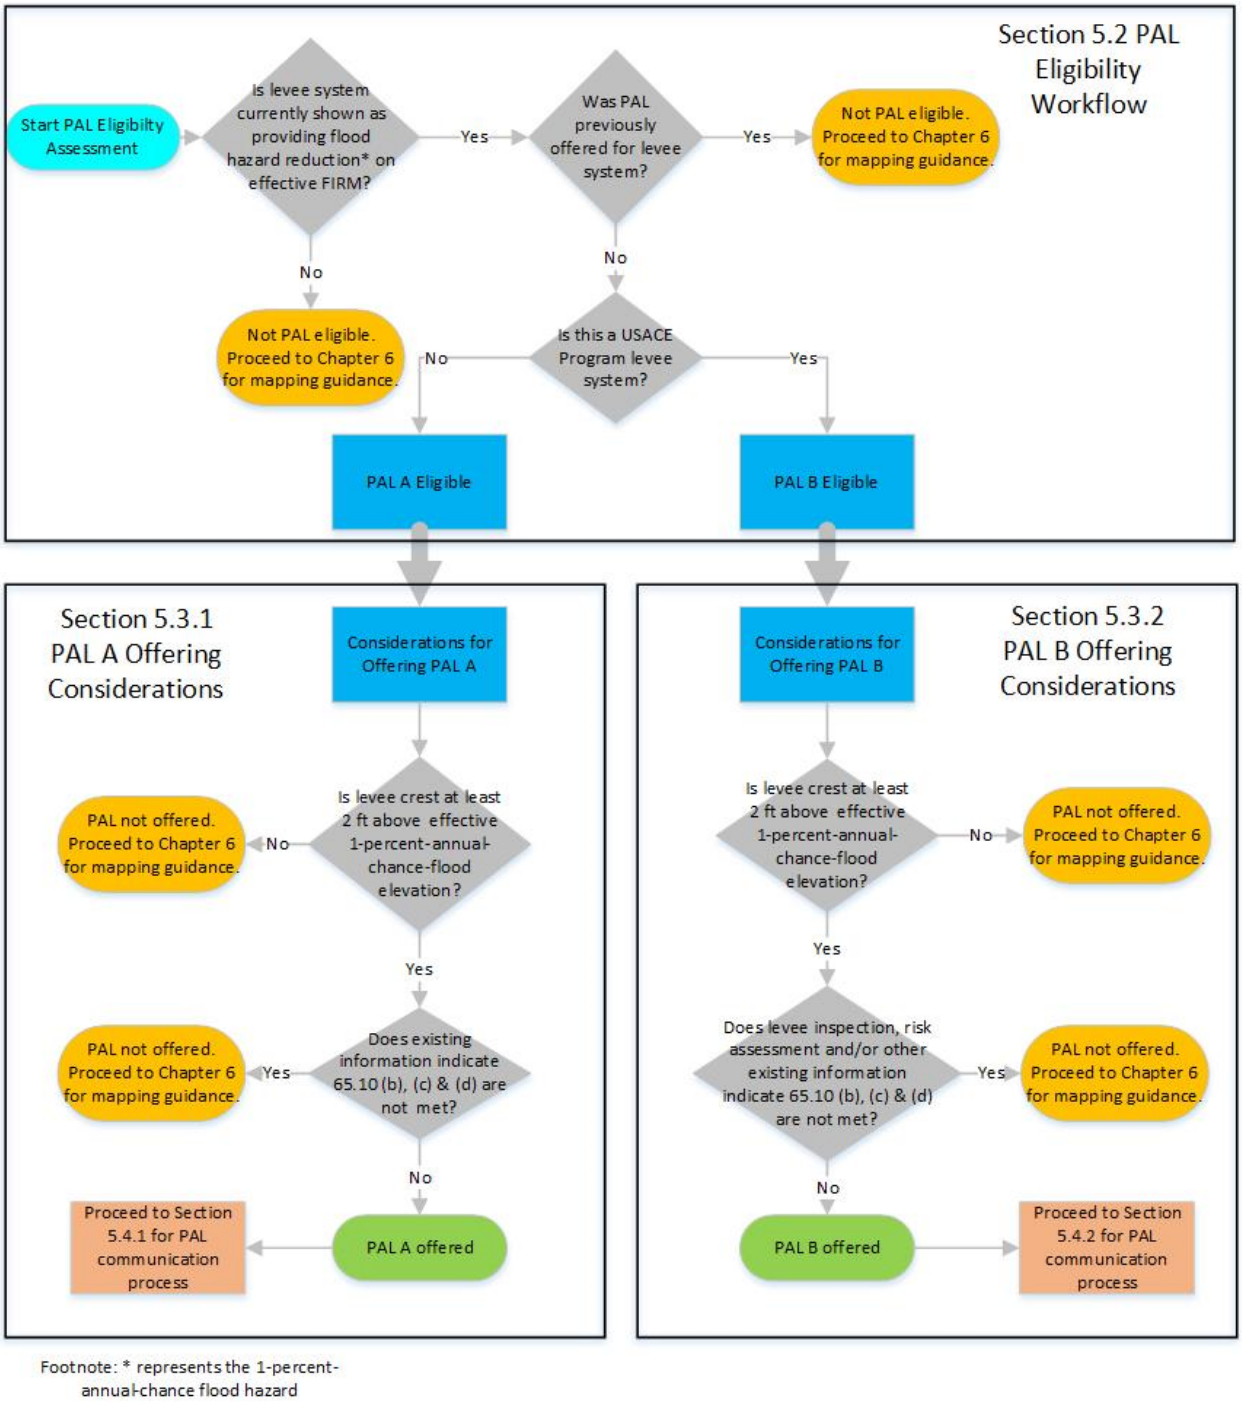

Figure 9: PAL Determination Decisions Tree

5.4 PAL Communication and Coordination Processes

This section discusses the communication and coordination processes followed by FEMA, Project Team members, levee owners, and USACE once a levee system has been identified as being eligible for a PAL designation per the criteria outlined in Sections 5.2 and 5.3 of this document. This section also discusses the required PAL submission and 44 CFR 65.10-required data and

documentation submission from the levee owner to FEMA. Levee systems not eligible for a PAL designation should be evaluated through analysis and mapping procedures for non-accredited levee systems and associated engagement. See Chapter 6 of this document for more information regarding non-accredited levee systems.

5.4.1 PAL Category A

The Project Team will prepare an initial notification letter for the FEMA Regional Office to send to the appropriate levee owner(s) to identify the levee system(s) that meet the criteria in Subsection 5.3.1 of this document and are, therefore, PAL eligible. The FEMA letter will describe the PAL category and the requirements and supporting documentation to enter a PAL agreement with FEMA.

The following attachments will accompany the initial notification letter sent to the levee owner(s) of non-USACE Program levee systems:

- A description of the requirements to meet 44 CFR 65.10
- An agreement to accept the PAL designation (agreement for Category A), for the levee owner(s) to sign and return to FEMA before the 91st day following the date of the initial notification letter. FEMA will send a similar agreement to levee-impacted community(ies).

Once the FEMA Regional Office sends the initial notification letter for Category A, the levee owner will have 90 days to return the PAL submission. The PAL submission requirements are as follows:

- An agreement signed by the levee owner(s) stating that the mapping of the PAL on a FIRM (PAL designation) is warranted because the levee system can be demonstrated to meet the requirements of 44 CFR 65.10, and that data demonstrating such will be provided to FEMA within 24 months. A similar, signed agreement must be provided by any levee impacted community(ies).
- A copy of the adopted operation and maintenance plan for the levee system.
- Records of levee system maintenance and operation, as well as tests of the mechanized interior drainage systems, if applicable.

Any levee owner that signs a PAL agreement must submit 44 CFR 65.10-compliant data and documentation within 24 months of the 91st day following the date of the initial notification letter. Levee owners may provide 44 CFR 65.10-compliant data to FEMA at any point within this 24-month timeframe and are encouraged to do so as soon as possible. In addition, the levee owner(s) must submit a progress report to FEMA 12 months after signing the PAL agreement to document progress toward obtaining 44 CFR 65.10-compliant data and documentation.

5.4.2 PAL Category B

The Project Team will prepare an initial notification letter for the FEMA Regional Office to send to the appropriate levee owner(s) to identify the levee system(s) that meet the criteria in Subsection 5.3.2 of this document and are, therefore, PAL eligible. A copy of this letter will be sent to the appropriate USACE District office for awareness. The FEMA letter will describe the PAL

category and the requirements and supporting documentation to enter a PAL agreement with FEMA.

The following attachments will accompany the initial notification letter sent to the levee owner(s) of USACE Program levee systems:

- A description of the requirements to meet 44 CFR 65.10, Mapping of Areas Protected by Levee Systems.
- An agreement to accept the PAL (agreement for Category B), for the levee owner(s) to sign and send back to FEMA before the 91st day following the date of the initial notification letter. FEMA will send a similar agreement to levee impacted community(ies).

When the levee system is fully or partially owned by USACE, FEMA will coordinate with the USACE District office and other levee owner(s), if any, to determine if the levee owner(s) intend to sign a PAL agreement.

Once the FEMA Regional Office sends the initial notification letter for Category B, the levee owner will have 90 days to return the PAL submission. The PAL submission requirements are as follows:

- An agreement signed by the levee owner(s) stating that the PAL designation is warranted because the levee system can be demonstrated to meet the requirements of 44 CFR 65.10, and that data demonstrating such will be provided to FEMA within 24 months. A similar, signed agreement must be provided by any levee impacted community.

Any levee owner that signs a PAL agreement must submit 44 CFR 65.10-compliant data and documentation within 24 months of the 91st day following the date of the initial notification letter. Levee owners may provide 44 CFR 65.10-compliant data to FEMA at any point within this 24-month timeframe and are encouraged to do so as soon as possible. In addition, the levee owner(s) must submit a progress report to FEMA 12 months after signing the PAL agreement to document progress toward obtaining 44 CFR 65.10-compliant data and documentation.

5.4.3 Timing of Initial Notification Letter

To minimize the risk of the PAL designation expiring prior to the effective date of the FIRM panel impacted by the PAL note, ideally the initial notification letter from FEMA should be timed such that the signed PAL agreements from levee owners and impacted communities are received before FEMA issues the Preliminary FIRM as indicated in Figure 10.
For example, an initial notification letter could be provided after KDP 2. This would allow the 90-day PAL offer period (beginning the date of the initial notification letter and ending 90 days later) to expire before the conclusion of the Quality Review 3 (QR3) review and the result of the PAL offer could be reflected on the Preliminary FIRM. Coordination with the QR3 reviewer may be necessary to allow the PAL note to be shown on the FIRM before the expiration of the PAL offer period and the QR3 review should not be deemed complete before to the 91st day past the date of the initial notification letter. This timing for the QR3 review to overlap the PAL offer period reduces, but does not eliminate, the risk of the 24-month PAL period expiring before the effective date of the FIRM.

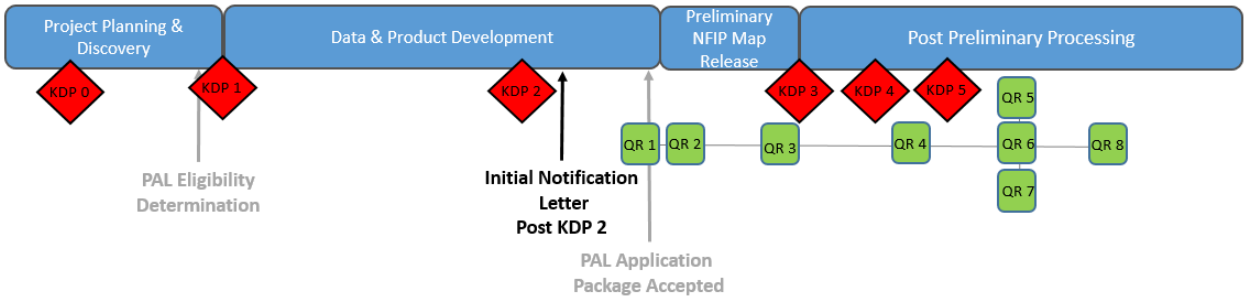

Figure 10: Initial Notification Letter within Risk MAP Project Timeline

5.4.4 Communication Guidance for PAL Submission Accepted by FEMA

This subsection provides guidance for communication to levee owners when FEMA accepts a PAL submission.

During the 24-month period that the PAL agreement is active (24-month PAL period), the FEMA Project Officer or designee will notify the levee owners and other stakeholders of the ongoing 24-month PAL period during which the levee owner must submit 44 CFR 65.10-compliant data and documentation to FEMA. This notification will be accomplished by sending a series of letters during the 24-month PAL period as follows:

- 30 days after initiation of the PAL agreement
- 10 months after initiation of the PAL agreement
- 16 months after initiation of the PAL agreement
- 90 days before the PAL period expiration date
- 30 days before the PAL period expiration date

Additionally, a progress report reminder letter will be sent to the levee owner to remind the owner that a progress report is due to FEMA 12 months after the start of the 24-month PAL period to document progress toward compliance with the PAL agreement.

The FEMA Project Officer or designee will send the letters to each levee owner signatory of the PAL Agreement, and will send copies of the letters to the following (at a minimum):

- CEOs of all impacted communities
- FPAs of all impacted communities
- State NFIP Coordinator(s)
- State levee safety officials, where appropriate
- District offices of U.S. Senators and U.S. Representatives
- USACE District offices, if the levee system is a USACE Program levee system

It is important that appropriate District offices of U.S. Senators and U.S. Representatives are aware of this communication effort throughout the 24-month PAL period, especially in advance of

the PAL period expiration date. Therefore, in addition to sending copies of the letters, FEMA Regional Offices shall notify their Regional Legislative Affairs Division who may coordinate additional outreach efforts, as appropriate.

The FEMA Project Officer may choose standard U.S. mail or certified mail to send the letters to the levee owners and impacted communities. Use of a tracking number and mail service website (such as USPS.com) is recommended for delivery tracking to confirm delivery of the letter. The FEMA Project Officer or designated Project Team member will file return receipts, fax reports, or phone logs documenting the follow up telephone calls in the case file for each affected community. The FEMA Project Officer or designated Project Team member will also include copies of the letters with other technical and administrative support data in the Technical Support Data Notebook (TSDN) for the project upon the expiration of the PAL period.

Additionally, the FEMA Project Officer should consider conducting an in-person PAL outreach meeting with the levee owner and other stakeholders to discuss:

- Status of the levee system
- Data collection process in support of submitting 44 CFR 65.10-compliant data and documentation to FEMA for contents only review and approval prior to the expiration date of the PAL period
- Analysis and mapping procedures for non-accredited levee systems, if applicable

The recommended timing of this meeting is near the time that the levee owner is to provide the 12-month progress report to FEMA.

The FEMA Project Officer or designated Project Team member will distribute and track the letters to each levee owner signatory of the PAL agreement and other federal, state, and local stakeholders.

5.4.5 Communicaton Guidance for PAL Submission Not Accepted by FEMA

Conditions may arise where FEMA has determined a levee system to be PAL eligible and offered a PAL designation, but then decides not to proceed with PAL designation for the levee system. If any of the following conditions occur, FEMA may decide not to accept the PAL submission:

- The signed PAL agreement is not returned to FEMA before the 91st day following the date of the initial notification letter.
- The PAL submission is determined to be deficient, such as:
    - A copy of the adopted operation and maintenance plan for the levee system is deficient or not provided.
    - For non-USACE Program levee systems, records of levee system maintenance and operation, as well as tests of the mechanized interior drainage systems, if applicable, are deficient or not provided.

5.4.6 Rescinding the PAL Designation

If any of the following conditions arise during the 24-month PAL period, FEMA may take immediate action to rescind the PAL designation and revise the FIRM for the area landward of the levee system:

- FEMA determines that the data and documentation required for compliance with 44 CFR 65.10 is deficient within 24 months of the 91st day following the date of the initial notification letter.
- The 12-month progress report is not provided to FEMA, and the FEMA Regional Office believes the PAL agreement should be rescinded.

If the FEMA Project Officer, based on the above criteria, concludes that a PAL designation should be rescinded before the expiration of the 24-month PAL period, the FEMA Project Officer will send a notification letter to the levee owner. The FEMA letter will clearly state the reason for rescinding the PAL designation and identify the levee system as non-accredited. See Chapter 6 of this document for more information regarding non-accredited levee systems.

5.4.7 Data and Documentation Submission for PAL Levee Systems in Support of 44 CFR 65.10

If a levee owner can provide 44 CFR 65.10-compliant data and documentation for a levee system to FEMA before the expiration date of the PAL, the levee system will be accredited and mapped accordingly, either within a current mapping project, or through a LOMR or PMR. The timing of the submission will impact FEMA's decision on the appropriate mapping process. Completeness regarding 44 CFR 65.10 requirements is discussed in Chapter 4.3.

FEMA will not grant extensions to the 24-month PAL period. However, accreditation opportunities for levee system are still available after the expiration date of the PAL agreement and before the Letter of Final Determination (LFD) for the update map showing the levee system not having base flood hazard reduction capability, if applicable.

If a levee owner can provide 44 CFR 65.10-compliant data and documentation and the submission is deemed complete by FEMA after the expiration date of the PAL agreement but before the effective date of the updated FIRM, FEMA will revise the FIRM and process it following the accreditation guidance provided in Chapter 4 of this document. This process does not provide an extension to the PAL period and may cause FEMA to spend funds to revise the FIRM to reflect the hazard of the non-accredited levee system, only to receive the submission and change direction to accreditation during the in-progress mapping project. However, this process provides consistency nationwide in initiating map revisions in a timely manner following the expiration of a PAL period.

If a levee owner provides the FEMA Regional Office with the 44 CFR 65.10 data and documentation submission and the data is deemed non-compliant by FEMA, the levee owner may submit additional data and documentation to substantiate compliance with 44 CFR 65.10. However, this data must be deemed compliant prior to the LFD date for the updated FIRM. If additional data and documentation submitted up to the day before the LFD date still do not meet the requirements of 44 CFR 65.10, FEMA may delay the FIRM. If issues with the data and documentation cannot be resolved, the flood hazard associated with the levee system should be

addressed through analysis and mapping procedures for non-accredited levee systems. See Chapter 6 of this document for more information regarding analysis and mapping procedures for non-accredited levee systems.

After the date of the LFD for the updated FIRM, a levee owner may provide 44 CFR 65.10-compliant data and documentation submission to FEMA for a completeness check through the LOMR or PMR process.

5.5 PAL Mapping and Notes

5.5.1 Mapping Project with PAL Designations

5.5.1.1 Cartographic Specifications for PALs

For levee systems with PAL designations, the levee-impacted area can still be mapped as Zone X (shaded) area with reduced flood hazard due to levee. The PAL designation associated with the Zone X (shaded) area with reduced flood hazard due to levee will be indicated on the FIRM panel with a PAL note. See FIRM Panel Technical Reference for more information regarding the depiction of flood hazard features and notes.

5.5.1.2 Notes to Users

For levee systems with PAL designations, the Notes to Users section of the FIRM directs map users to additional information about provisionally accredited levee systems. This note shall be on all FIRM panels that contain PALs. See FIRM Panel Technical Reference for more information regarding the FIRM Levee Notes to Users for PALs.

The Notes to Users example in FIRM Panel Technical Reference includes blanks in the note for the Project Team member to populate with the end date of the PAL period for the levee system associated with the flood zone.

See Subsection 5.4.1.6 and FIRM Database Technical Reference for more information regarding the S_Levee Table.

5.5.1.3 FIRM Panel Index

The Project Team does not need to revise the FIRM Panel Index due to a PAL designation. The Project Team does not need to revise and update the FIS Report to identify and include the levee systems that have a PAL designation. The Levees table in the FIS Report should show all accredited, provisionally accredited, and non-accredited levee systems. See FIS Report Technical Reference for more information regarding the Levees table of the FIS Report.

5.5.1.4 FIRM Database

The FEMA FIRM Database stores the digital GIS data used in the map production process, as well as tabular information inside the FIS Report.

The S_Levee table, part of the FIRM Database, contains information about levee systems shown on the FIRMs, including levee systems with PAL designations. For levee systems with PAL designations, the S_Levee table contains a field to be populated with the end date of the PAL period for the levee systems associated with the flood zone. The end date of the PAL period for

the levee system is 24 months from the start date of the PAL period. If the date is not known, the assigned Project Team member can obtain this date through consultation with FEMA Project Officer or other Regional Office staff. For more information regarding the S_Levee table, see FIRM Database Technical Reference.

5.5.1.5 Flood Risk Products

The L_Levee_Scenario table describes scenarios modeled for levee systems in the Flood Risk Database. The table contains a field to be populated by the Project Team member with levee system accreditation status, which includes the option of PALs. See Flood Risk Database Technical Reference for more information regarding the L_Levee_Scenario table. For a list of acceptable values for levee accreditation status, see the D_Levee_Accreditation domain in Domain Tables Technical Reference.

5.5.2 Mapping Project with Expired PAL Designation

For mapping projects that contain levee systems with expired PAL designations, the Project Team should address the flood hazard associated with the levee system following the analysis and mapping procedures for non-accredited levee systems summarized in Chapter 6 of this document; however, depicting levee systems with expired PAL notes on Preliminary or effective FIRMs may be appropriate in limited situations. It is a standard that the justification to use an expired PAL agreement date on the FIRM panel must be approved by the FEMA Region and FEMA Headquarters.

If approval is obtained from FEMA Region and FEMA Headquarters to include an expired PAL note on an effective FIRM, the Project Team should follow the guidance in Subsection 5.5.1 of this document.

6.0 Non-Accredited Levee Systems

This chapter provides guidance to FEMA Regional Office staff, FEMA Risk MAP providers, CTPs, and CTP providers involved in performing Flood Risk Projects where non-accredited levee systems have been identified. The FEMA, provider, and CTP staff involved in these "non-accredited levee projects" are hereinafter referred to as "Project Teams". An overview of the process described in this chapter is shown in Figure 11 on page 72.

6.1 Non-Accredited Levee Systems Defined

Non-accredited levee systems are systems that do not meet the NFIP regulatory requirements of 44 CFR 65.10 as described in Chapter 4 of this document and that are not shown on a FIRM as reducing the base flood hazard. This process for non-accredited levee systems will not be applied to non-levee features (discussed in Chapter 7 of this document), levee systems that are not hydraulically significant, or coastal structures[2] that reduce the flood hazard to areas below sea level. For mapping purposes, a structure is considered hydraulically insignificant if, during a base flood event, the peak water-surface elevations landward of the structure may be the same regardless of whether the structure was in place.

[2] For coastal structures, such as seawalls, revetments, and bulkheads, the USACE Coastal Engineering Research Center (CERC) prepared Technical Report CERC-89-15, Criteria for Evaluating Coastal Flood Protection Structures, in December 1989.

The technical procedures described in this document may be used for non-accredited levee systems that are not hydraulically significant, but the process as a whole does not apply.

6.2 Other Considerations

Subsections 6.2.1 through 6.2.5 provide information regarding the submission of data through the LOMR process, coastal considerations, expiring PAL system designations, projects involving multiple levee systems, and projects involving levee systems that are in the process of being restored.

6.2.1 Submission of Data through the Letter of Map Revision Process

Mapping of non-accredited levee systems may be completed following the MT-2 process for LOMRs provided that the requester follows the guidance for analysis and mapping procedures for non-accredited levee systems as outlined in this document. Before submitting the LOMR request, the community FPA or designee establish a Local Levee Partnership Team (LLPT) with participation of stakeholders, including FEMA, based on the complexity and scope of the levee system under evaluation. The organizer of the LLPT must document the options discussed by the LLPT members and FEMA decisions regarding the appropriate analysis and mapping procedures to be used. So that all stakeholders are included in the map revision process, the organizer or designee will make copies of these documents available directly or through a publicly accessible website. Upon completion of a Levee Analysis and Mapping Plan, discussed in Section 6.7 of this document, the requester can submit a request for a LOMR.

6.2.2 Coastal Considerations

Flood Risk Projects involving non-accredited levee systems in coastal areas may have a longer timeline for completion than a “typical” levee-related Flood Risk Project in a riverine or lacustrine setting.

The Project Team also may need to assess and discuss the transition zones between coastal and riverine levees. Additional information regarding coastal considerations is provided in the discussion of each of the technical procedures in Subsections 6.11 through 6.15 of this document.

6.2.3 Expiring Provisionally Accredited Levee Designations

Because extensive coordination may have been performed as part of the PAL process (see Chapter 5), the Project Team may not need to carry out some outreach and data collection for levee systems where PAL designations are expiring. Where outreach and data collection activities are necessary, the Project Team is to perform these tasks in conjunction with the remaining parts of the PAL process. For example, the Stakeholder Coordination and Data Collection Meeting (discussed in Section 6.4) may be combined with the PAL Meeting (discussed in Subsection 5.4.4) to discuss whether the PAL status or designation is expiring, along with potential options to address the levee. The FEMA Project Officer will make this determination through coordination with other Project Team members at the appropriate time to incorporate the FEMA levee analysis and mapping procedures for non-accredited levees into the project timeline.

6.2.4 Projects Involving Multiple Levee Systems

If levee systems have been constructed on both sides of a flooding source, or if multiple levee systems overlap, the Project Team will analyze the extents of the natural valley area and reach-specific flood hazards for each system independently, assuming the other system remains in place.

6.2.5 Levee Restoration and Adequate Progress

Situations may occur where FEMA determines, through coordination with community officials, levee owners, and/or OFAs), that a restoration (Zone AR, 44 CFR 65.14) or adequate progress (Zone A99, 44 CFR 61.12) project for the levee is underway. In these instances, levee reaches are not used. Rather, the regulatory requirements provided in 44 CFR 61.12 for new construction projects that have made adequate progress toward completion or the regulatory requirements provided in 44 CFR 65.14 for de-accredited levee systems that are being restored to provide base flood event design, or greater, would apply. Section 100230 of the Biggert-Waters Flood Insurance Reform Act of 2012 (Public Law 112-141) provides additional guidance on reconstruction or improvement of flood hazard reduction systems. Additional guidance is provided in Guidance Document No. 34, Guidance for Flood Risk Analysis and Mapping: Zone A99 and Zone AR Determinations, which is accessible from the FEMA Guidelines and Standards for Flood Risk Analysis and Mapping webpage

6.3 Levee Analysis and Mapping Procedure

Under the FEMA levee analysis and mapping approach followed before FEMA issued guidance in July 2013, FEMA analyzed and mapped a levee system that did not meet the NFIP requirements of 44 CFR 65.10 as if it had no effect on flooding on the landward side of the levee system during the base flood. This was known as the “without levee” approach.

The FEMA document titled Analysis and Mapping Procedures for Non-Accredited Levee Systems, issued in July 2013, provides additional information on the process used by FEMA to analyze and map areas on the landward side of non-accredited levee systems that are shown on FIRMs. The document, which is accessible from the FEMA website (https://www.fema.gov/media-library-data/20130726-1922-25045-4455/20130703_approachdocument_508.pdf), provides:

- A synopsis of FEMA’s historic analysis in the vicinity of levee systems
- An overview of the development process and teams responsible for procedure development
- Response to the public comments received and incorporated
- An understanding of analyses and mapping approaches

The technical aspects of Analysis and Mapping Procedures for Non-Accredited Levee Systems have been incorporated into this document.

Given recent technological advances in data collection and H&H modeling, FEMA can implement a more refined approach to mapping flood hazards in areas landward of levee systems. The current levee analysis and mapping procedures were developed to analyze and map areas on the landward side of non-accredited levee systems that are shown on FIRMs. The current levee

analysis and mapping procedures better meet the needs of the public and provide results that are more refined.

The current FEMA levee analysis and mapping procedures for non-accredited levee systems provide for a repeatable and flexible approach that:

- Complies with all existing statutory and regulatory requirements governing the NFIP, most notably the requirements of 44 CFR 65.10
- Leverages local input, knowledge, and data through proactive stakeholder engagement
- Aligns available resources for engineering analysis and mapping commensurate with the level of hazard in the areas landward of levee systems
- Recognizes the uncertainty associated with levee systems
- Allows analysis of levee reaches
- Considers, from an engineering perspective, the unique characteristics of each levee system

Figure 11 illustrates the current FEMA levee analysis and mapping procedures for non-accredited levee systems. Guidance on the identification of the levees is detailed in Section 3.3 of this document. Following confirmation that a structure is a levee; the Project Team conducts an initial accreditation evaluation to determine if the levee system is accredited or can be provisionally accredited. If neither, then the Project Team analyzes the levee system following the levee analysis and mapping procedures illustrated in Figure 11.

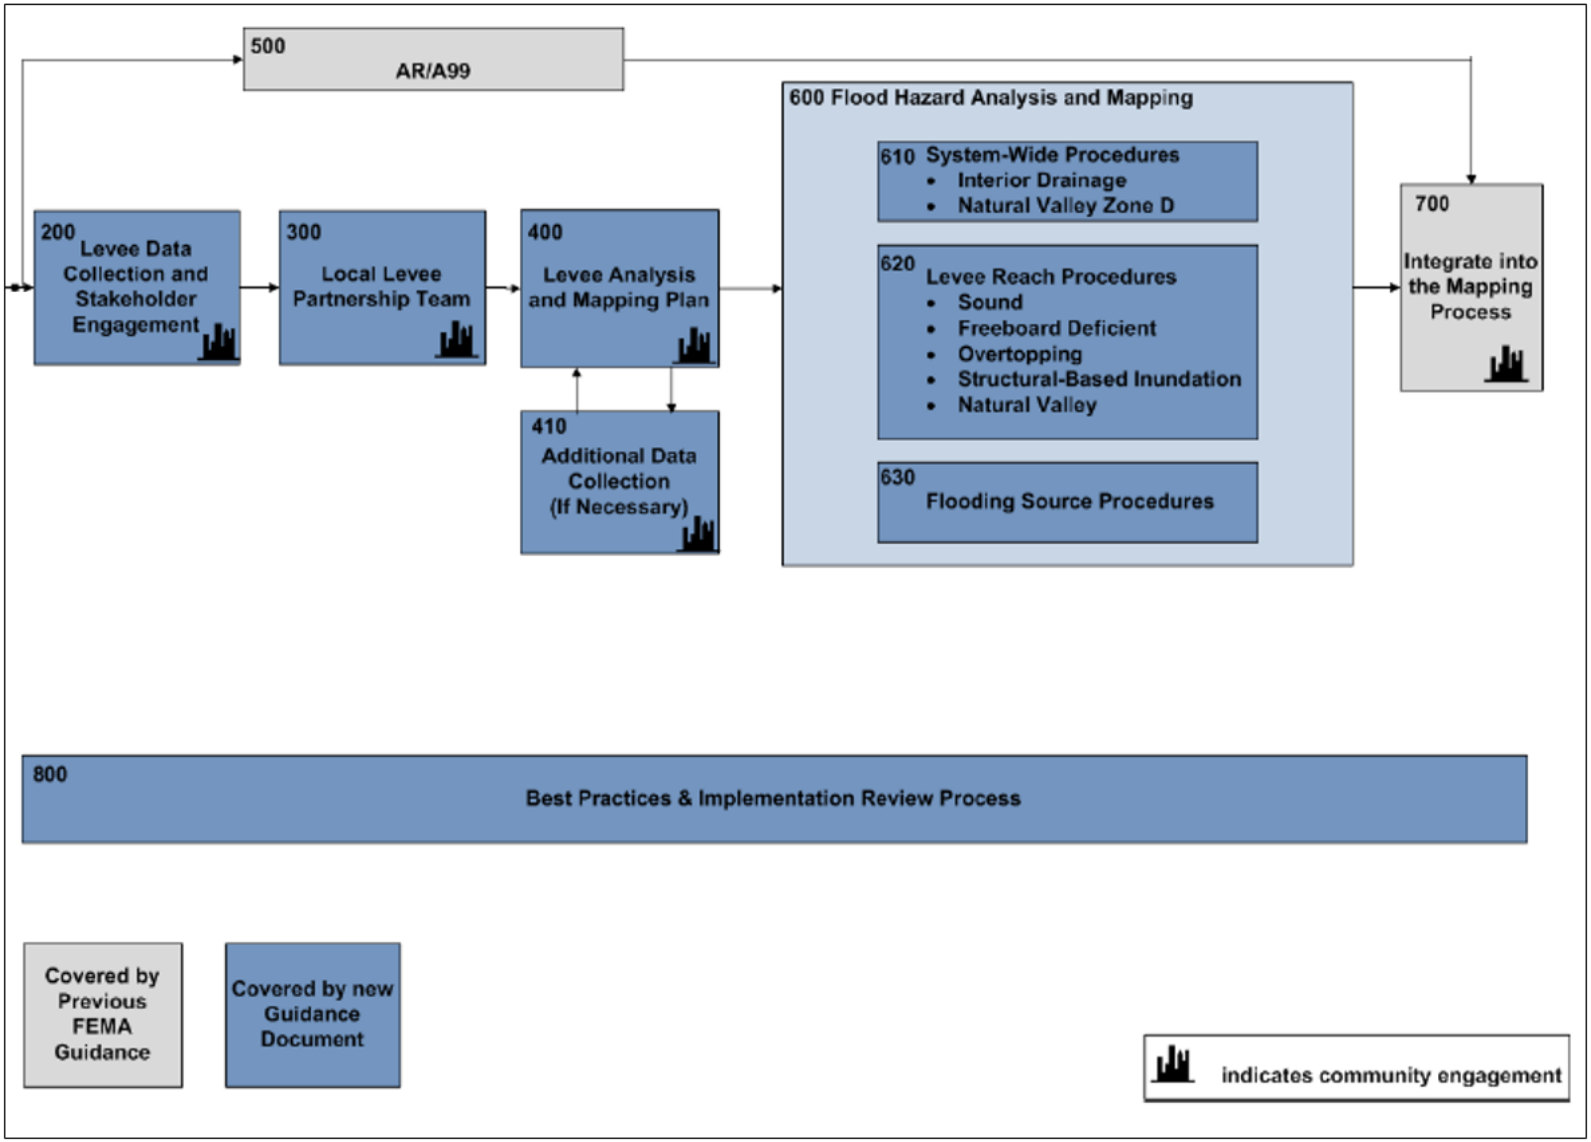

Figure 11: FEMA Levee Analysis and Mapping Procedure

6.4 Levee Data Collection and Stakeholder Engagement (Figure 11, Element 200)

The FEMA analysis and mapping procedures for non-accredited levees include an interactive coordination process with key stakeholders, including State and community officials, officials of participating Tribes, and levee owner(s). The primary goals of the levee data collection and stakeholder engagement phase are:

1. Improve stakeholder understanding of the levee analysis and mapping process.
2. Help the Project Team obtain a comprehensive understanding of data available and the levee system(s) in project areas so that informed decisions may be made by FEMA regarding the procedures to be used to model and map flood hazards for non-accredited levee systems.

FEMA has developed email and letter templates that the Project Team may use when inviting community stakeholders to meet with the LLPT. Project Team members may obtain copies of Region-specific templates through the FEMA Project Officer.

FEMA Regional Office staff are to plan, and budget for, stakeholder coordination, data collection, and establishment of an LLPT for all Flood Risk Projects involving non-accredited levee systems. Each step is discussed in this document. If little or no data are available, or if the Natural Valley Procedure discussed in Subsection 6.10.1 of this document is preferred by the affected communities and that preference is documented, the scope may be limited. This stakeholder coordination step should typically occur during the Discovery process for the watershed/project area that is the focus of the Flood Risk Project.

The Project Team will perform the initial levee stakeholder coordination and data collection steps for all non-accredited levee systems. In some instances, the results of these data collection efforts may indicate that the data and documentation already collected are adequate and are sufficient to make a decision on potential analysis and mapping procedures. Where applicable, such a decision will be made by the FEMA Project Officer with input from the LLPT. The primary function of the LLPT will be to provide feedback, additional data, and options on levee reach selection for the system. Additional information on the LLPT is provided in Section 6.5 of this document. Thereafter, FEMA, through coordination with community officials, Tribal officials, levee owner(s), and local project sponsor(s), will proceed with modeling the levee system and mapping the flood hazards in areas landward of the levee system. (See Figure 11, Elements 500 and 600.)

The levee data collection and stakeholder engagement process are shown in Figure 12 and discussed in more detail in Subsections 6.4.1 through 6.4.4.

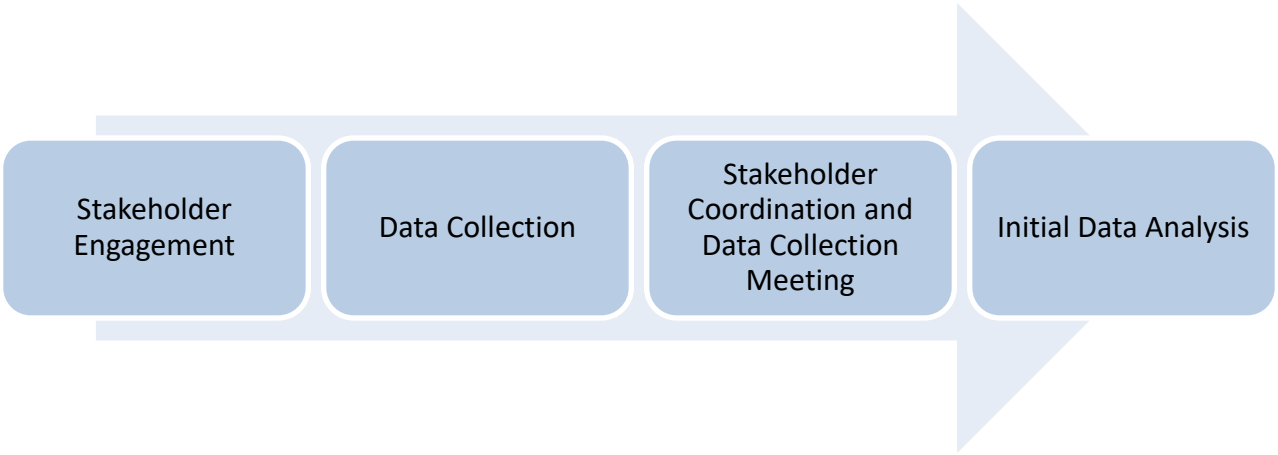

Figure 12: Levee Data Collection and Stakeholder Engagement Process

6.4.1 Stakeholder Engagement

The FEMA Project Officer or designee will engage levee-impacted communities, levee owners/operators, and levee sponsors during the stakeholder engagement process. The purpose of this initial engagement is twofold:

1. Discuss the levee analysis and mapping process.
2. Collect initial community- and levee system-related information and data to help streamline and facilitate future meetings. This upfront coordination may take the form of conference calls, Web-enabled meetings, or other means that facilitates two-way communication.

For a Flood Risk Project involving a non-accredited levee system, the Project Team will need to engage with a different array of community, county, regional, and State officials and other stakeholders than may be engaged for a Flood Risk Project that does not involve such systems. The stakeholders to be engaged include, but are not limited to, the following:

- Community, County, and State emergency management officials
- Levee owners/operators
- Officials from communities upstream of, downstream of, and across the flooding source from the levee system
- State or regional groups with a vested interest in water resources, such as levee boards, conservation districts, and watershed/river basin commissions
- Dam safety officials
- Members of Tribal communities, as defined through consultation and coordination with Tribal officials
- GIS managers and specialists, community and regional planners, and county land use departments

- Representatives of district offices of OFAs with responsibility for levee systems in the project area, including USACE District offices
- Economic development and commerce representatives
- Members of the local engineering community

This upfront coordination may take the form of conference calls, Web-based meetings, or other means of two-way communication. The types of levee stakeholders engaged in a levee-related project may vary by State or Region but may include local community and Tribal officials and agencies, local economic development organizations or environmental groups, members of the local engineering community, State, and regional representatives, USACE, and OFAs.

6.4.2 Data Collection

The Project Team will obtain available supporting data and documentation for the levee system elements from levee system owners; levee system operators; State agencies; local agencies; private individuals or corporations; FEMA data repository and online services; and USACE, including the NLD; and OFAs. The Project Team may perform some of this data collection before an initial meeting with levee stakeholders. This data collection effort before the meeting will help FEMA facilitate and encourage substantive discussion during the meeting. In addition, the Project Team will obtain available supporting documentation regarding historical performance of the levee system, considering both successful performance and unsuccessful performance issues.

Collecting data and information early in the process will help the Project Team facilitate and encourage substantive discussion during meetings with stakeholders. Data collection efforts may vary based on the uniqueness of the levee system. FEMA will not fund any efforts related to certifying data for levee accreditation or making determinations of the levee's structural conditions. Levee owners may choose to perform additional data collection activities but must do so at their own expense. The Project Team will work with various stakeholders as appropriate to obtain supporting data and documentation. The Project Team will make the data and documentation available to those who request it.

Depending on the complexity of the levee system, data and documentation collected may include (if available and applicable), but are not be limited to, the following:

- Design reports/memorandums
- Construction documentation reports/memorandums, specifications, or plans
- Post-construction plans and specifications (e.g., bridges, roads, utility construction that occurred since levee construction)
- Survey data
- Geotechnical reports
- Structural analyses
- Interior drainage analyses
- O&M plans

- Inspection reports
- Historical news articles or data regarding levee breaches and flood fighting efforts and levee distress
- USACE NLD data, Levee Screening, or Risk Assessment Reports
- Flood records and streamflow data
- Current orthophotography and topographic data
- Related data from the FEMA MIP, the FEMA Engineering Library, and other FEMA archives/databases
- Building footprint/parcel data
- Master drainage plans and/or flood modeling
- PAL or accreditation review documentation

Project Team members are to use the NLD as a first resource, if available. The data and information collected will help FEMA and the levee stakeholders develop an approach for modeling and mapping the flood hazard in areas landward of non-accredited levee systems.

Typically, the FEMA Project Officer will make the initial contact with district offices of OFAs to obtain data and information regarding levees. The Project Officer will determine the appropriateness of followup contacts with OFAs by other Project Team members. Data and information collection efforts may also vary based on the potential uniqueness of each area landward of a levee system. The FEMA Project Officer and other Project Team members will work with various stakeholders in these areas to obtain the best available supporting data, information, and documentation. Levee owners may choose to perform additional data and information collection activities but must do so at their own expense.

The Project Team is to develop and maintain a distribution list for disseminating information to all stakeholders involved in the process and maintain this list throughout the lifecycle of the project

If, during the data collection effort, information and documentation is provided substantiating that the levee system may be accredited, FEMA will reconsider the accreditation determination following the guidance discussed in Chapter 4 of this document.

6.4.3 Stakeholder Coordination and Data Collection Meeting

An in-person meeting with stakeholders, referred to as the Stakeholder Coordination and Data Collection Meeting, is vital during the data collection phase of a levee mapping project. Information on the objectives, timing, attendees, messages to be delivered, pre- and post-meeting activities, and field reconnaissance efforts related to the meeting is provided in Subsections 6.4.3.1 through 6.4.3.7.

6.4.3.1 Meeting Objectives

The overarching objectives of the Stakeholder Coordination and Data Collection Meeting are:

- To introduce stakeholders to each other

- To discuss areas of flood risk, available data, and the FEMA process for analyzing and mapping flood hazards landward of non-accredited levees

To accomplish these objectives, the Project Team performed the upfront research and data and information collection activities described in Subsection 6.4.2. This first meeting is a working meeting, so it is important that attendees are prepared to contribute and that the meeting facilitator and other Project Team members encourage participation.

A comprehensive list of the meeting objectives is included below. It may not be possible to cover these objectives at every stakeholder meeting. However, this list includes the array of topics that may be discussed depending on the levee system.

- Introduce the Project Team to the community officials, Tribal officials, and other stakeholders with areas of influence within the areas potentially impacted by a new levee analysis and mapping project.
- Emphasize that the goal of the levee analysis and mapping project is to apply the technical procedure that best reflects the flood hazard in the area landward of the levee based on available resources, data, and community needs.
- Review available data on the levee system, confirm whether the data are accurate, and obtain stakeholders' perspectives about their flood hazards. This will help determine the appropriate procedure for modeling the levee system.
- Emphasize the importance of the stakeholders' responsibility in providing necessary data and keeping the public informed of flood hazards and the relevance of those hazards.
- Discuss floodplain management and flood insurance implications of the use of Zone D as the flood hazard designation on the FIRM.
- Discuss potential members of an LLPT, which is discussed in more detail in Section 6.6 of this document.

6.4.3.2 Meeting Timing

The Project Team is to hold the Stakeholder Coordination and Data Collection Meeting after Project Team members have collected available data, documentation, and information and have had initial discussions with identified stakeholders. The Project Team will plan the Stakeholder Coordination and Data Collection Meeting in coordination with the affected community officials, Tribal officials, and levee owner(s)/operator(s).

6.4.3.3 Meeting Attendees

The Project Team is to invite all stakeholders contacted during the levee data collection and stakeholder engagement process to the Stakeholder Coordination and Data Collection Meeting. It may not be possible for all stakeholders to attend all meetings. However, their input is important, and Project Team members should attempt to coordinate with these stakeholders in advance of the meeting if their attendance is not feasible or to arrange for remote participation when necessary. Additionally, Project Team members are to ask stakeholders for suggestions of other stakeholders who should be included in the Stakeholder Coordination and Data Collection

Meeting and any subsequent meetings. Project Team members are to follow up on meeting outcomes and actions with those stakeholders who are not able to attend in person or remotely.

6.4.3.4 Meeting Messages

Messages that are to be emphasized during the Stakeholder Coordination and Data Collection Meeting include, but are not limited to, the following:

- The levee analysis and mapping approach is a process with a variety of options, where the stakeholders are actively engaged in the process.
- The goal of the levee analysis and mapping project is to apply the procedure that best reflects the flood hazard in the area landward of the levee system based on available resources, data, and community needs.
- It is important for community officials to keep the public informed of flood hazards and associated risks and the relevance of those risks and identifying the public as a stakeholder in the process.
- The use of Zone D landward of the levee system has both floodplain management and flood insurance implications.
- Some risk of flooding will always exist landward of a levee system.
- Additional information is available from the Living with webpage on the FEMA website, available at https://www.fema.gov/flood-maps/living-levees

6.4.3.5 Pre-Meeting Activities

Meeting-related actions and materials that the Project Team is to compile before the Stakeholder Coordination and Data Collection Meeting include, but are not limited to, the following:

- Coordinate with stakeholders upfront to obtain data; understand the levee system being assessed and its history; and to learn about a community's or Tribe's resources, assets, future plans, vision, etc.
- Confirm best available data (including the timing of such data) and discuss data-sharing agreements.
- Prepare talking points to discuss the levee system, the levee analysis and mapping approach, and the project lifecycle.
- Prepare NFIP compliance/adoption information as appropriate.
- Arrange for a field reconnaissance visit during the Stakeholder Coordination and Data Collection Meeting if appropriate.
- Prepare and distribute a meeting invitation, meeting agenda appropriate for the levee system, and map for discussion purposes.

The FEMA Project Officer, the FEMA Regional Tribal Liaison, or other FEMA Regional Office staff will identify any additional items that may be needed when Tribal nations are affected through consultation and coordination with Tribal officials.

6.4.3.6 Meeting Activities

Stakeholder Coordination and Data Collection Meeting activities include, but are not limited to, the following:

- An interactive, collaborative discussion. Project Team members are to facilitate discussions between community officials and other stakeholders, offer suggestions, and manage the time.
- Review of available data. Project Team members are to make a map providing a system-wide view of available data gathered to date available in GIS format. The GIS format allows a Project Team member to zoom in and out to specific, targeted areas for discussion purposes during the meeting.
- Identification of gaps in data collected. Project Team members are to work with meeting participants to identify data gaps that need to be filled and formulate a reasonable plan or alternatives, to fill the gaps especially if filling the gap is critical to project completion.
- Discussion of the procedures for analyzing and mapping the levee system(s) that are the focus of the project. Project Team members are to present the information in a logical way that illustrates the levee system(s) and the currently available and potentially available data. This will allow the majority of the meeting time to be focused on gaining a better understanding of the next steps for all participants.

6.4.3.7 Field Reconnaissance

In some instances, the Project Team may participate in a field reconnaissance of the levee system after the Stakeholder Coordination and Data Collection Meeting. The FEMA Project Officer will decide the type and level of field reconnaissance based on project needs and available resources.

Field reconnaissance generally is recommended along reaches where the Overtopping Procedure (discussed in Subsection 6.10.3 of this document) or the Structural-Based Inundation Procedure (discussed in Subsection 6.10.2 of this document) could potentially be used to model and map a levee reach. The field reconnaissance effort may be a drive along the levee system or a walk on top of the levee system to view areas of interest. The Project Team is to document the field reconnaissance using notes, markups, sketches, and/or photographs.

The field reconnaissance is not an inspection or an attempt by the Project Team to make technical conclusions on the quality, substance, or performance of the levee system. The primary purpose of the field reconnaissance is for the Project Team to gain a better understanding of the levee system to reflect the flood hazard information on the FIRM in areas landward of the levee system. FEMA analyses for flood hazard mapping do not predict or guarantee the performance, reliability, or overall safety of a levee system and are used only to identify the flood hazards landward of the levee system.

6.4.4 Initial Levee Data Analysis

The Project Team will analyze the collected data, information, and documentation to prepare for the LLPT Meeting(s). By performing this data analysis, the Project Team will be better prepared for specific discussions with the LLPT members about levee system history, characteristics, modeling procedures available, flood hazards, flood hazard communications, and outreach. The

FEMA Project Officer will determine the appropriate level of effort for this activity; the level of effort should be commensurate with the level of risk to the community, the complexity of the levee system, and the available data. Two main efforts may occur during this step.

1. The Project Team will analyze currently available and potentially available data to determine what reach-specific procedures could potentially be applied to the levee system(s) being analyzed. For example, if data to meet the structural requirements is not available and not expected to be available, the LLPT Meeting discussion should be focused on both the Natural Valley and Structural-Based Procedures.

2. The Project Team will conduct an analysis to determine baseline estimates and expected ranges of the SFHA extent and depth. This will usually include a Natural Valley analysis, evaluation of levee crest elevations, or the use of previously developed preliminary flood hazard zone boundaries. A rough analysis using the Structural-Based Inundation Procedure may be included as well. The Project Team will perform the analysis using readily available data, such as topographic data from the USGS National Elevation Dataset (available at https://nationalmap.gov/elevation.html) or more detailed data from the community.

As part of this initial Natural Valley analysis, the Project Team will develop 1-percent-annual-chance flood elevations by one of the following methods:

- Use the effective analysis.
- Prepare a Base Level analysis that applies the effective or a proposed flood discharge with a Base Level hydraulic model.
- Extend the effective BFEs landward of the levee.

In most situations, extending BFEs landward of the levee system represents a worst-case scenario for defining the limits of the SFHA. The Project Team will develop water-surface elevations for discussion purposes only, and the Project Team is to clearly inform the LLPT members that the final BFEs and SFHA delineations that will be shown on the FIRM may not match the results of this initial data analysis.

To show the results of this analysis, the Project Team will select depth profile locations to communicate the variability resulting from the various procedures as shown in Figure 13. For example, in Figure 13, the initial data analysis indicates that no single approach results in the shallowest depths landward of the levee. At the upstream end, the red area is the area where a Natural Valley analysis results in the deepest depths. In the central part of the levee (yellow area), however, the Natural Valley analysis results in the lowest depths, and the Structural-Based Inundation analysis results in the deepest depths. This initial analysis will provide the LLPT with an early indication of what the results from various types of analyses might provide.

The Project Team is to present the results through maps and a draft version of the Levee Analysis and Mapping Plan that summarizes the methods used and results. The Project Team will use the draft maps and draft plan to facilitate discussions with the LLPT regarding the available data and the range of potential outcomes. The FEMA Project Officer will provide templates for the draft maps and plan.

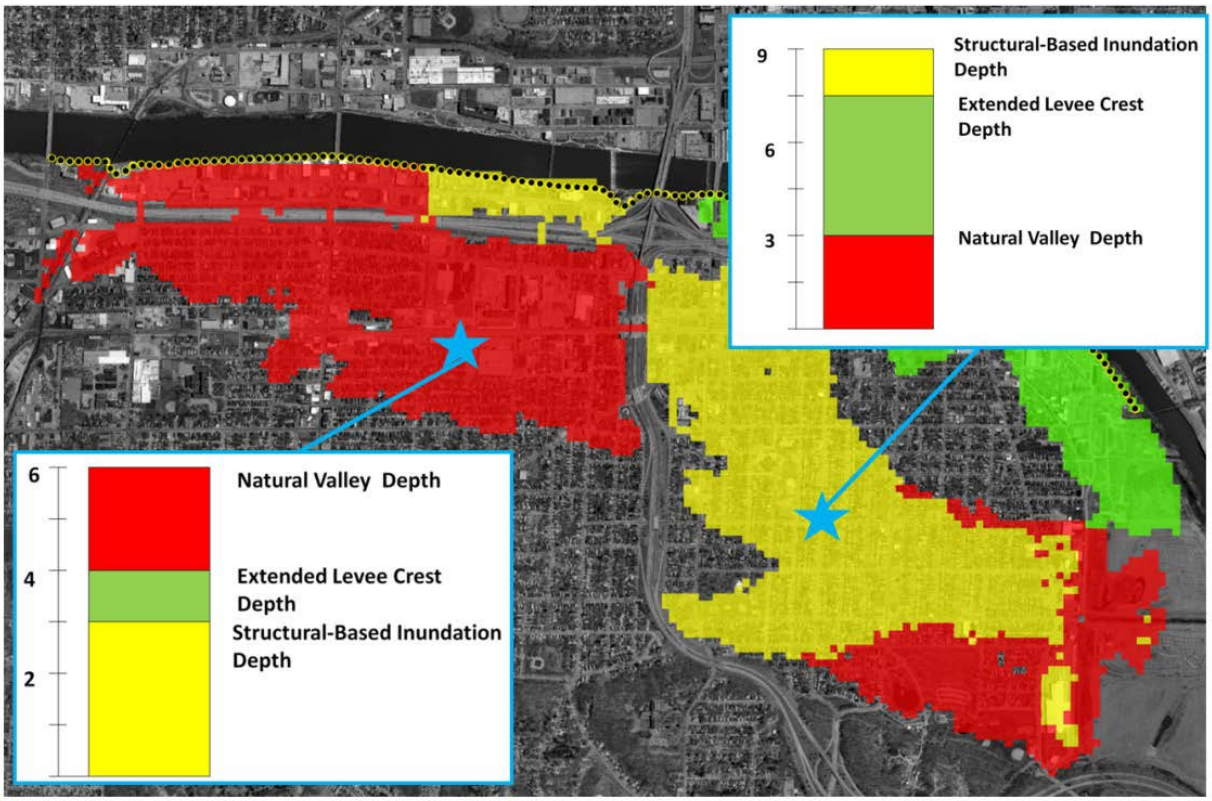

Figure 13: Sample of Potential Inundation Extents

6.5 Local Levee Partnership Team (Figure 11, Element 300)

6.5.1 Introduction and Mission

The levee analysis and mapping procedures provided for an interactive coordination effort with stakeholders, especially the key stakeholders that are invited to participate in the LLPT. A LLPT must be established with participation of diverse stakeholders based on the complexity and scope of the levee system under evaluation. The options discussed by the LLPT members and the decisions by FEMA regarding the appropriate analysis and mapping procedures to be used, must be documented, and made available to stakeholders. Participants in the LLPT will vary, depending on the scope and complexity of the levee system that is being analyzed and mapped.

The primary function of the LLPT will be to provide feedback and, if necessary, additional data, information, or documentation. The role of the FEMA Project Officer or other Regional Office representative as the facilitator of the LLPT will be to present results of the initial levee data analysis and any subsequent analysis, solicit and consider input from other LLPT members, and make the final decision on the technical procedure(s) to be applied to effectively analyze and map the flood hazards in the area landward of the levee system.

In consultation with the other LLPT members, the FEMA Project Officer or other Regional Office representative will determine the number and format for the LLPT meetings and coordination activities.

6.5.2 Transparency

The LLPT membership and activities must be transparent. To maintain this transparency, an assigned LLPT member or other designee is to create an attendance sheet documenting invitees and members attending meetings (in person, by telephone, or via the Web). In addition, the LLPT is to prepare meeting minutes that document important discussions, action items, and decisions made by FEMA. The LLPT is to make these documents available to stakeholders by U.S. mail, email, or postings to a publicly accessible website.

6.5.3 Membership

During the Stakeholder Coordination and Data Collection Meeting, the FEMA Project Officer or other Regional Office representative will explain the need for the LLPT and the types of individuals who could be members. The Project Officer or other representative from the FEMA Regional Office will always be a member of the LLPT but may not always attend meetings in person.

Once established, FEMA will provide outreach and training materials to enhance the ability of the LLPT members to meet their objectives successfully. For most projects, LLPT members will be a subset of those stakeholders that participated in the Stakeholder Coordination and Data Collection Meeting.

At minimum, all communities and tribes affected by flooding related to how the levee is analyzed and mapped will have the opportunity to have a participating member on the LLPT. If a community or tribe does not own or operate the levee in question, levee owners/operators will also have an opportunity to participate.

The following are the types of groups and individuals that could be invited to participate in the LLPT:

- Community CEO or designee (individual with decision-making authority, if not the CEO)
- CEO or designee of participating tribe (individual with decision-making authority)
- Community FPA
- Tribe FPA
- State NFIP Coordinator
- Levee owner and/or local project sponsor (if levee is not owned by a community)
- Local engineer/technical representative invited by the community
- FEMA Regional Office representative
- Representatives of OFA district offices that could provide additional input
- Other Project Team members (i.e., CTPs, FEMA Risk MAP providers, CTP subcontractors)
- Others as determined jointly by the community and FEMA Regional Office representative

6.5.4 Roles and Responsibilities

The FEMA Regional Office representative will coordinate with the LLPT, obtain LLPT member input, and make final decisions on the way to analyze and map the flood hazards in the areas landward of the levee system. The FEMA Regional Office representative will decide how reaches of the levee system are analyzed and mapped.

The Project Team will perform the levee analyses and mapping activities as directed by the FEMA Regional Office representative. This may include preparing the initial data analysis, as well as developing intermediate flood risk products. As previously stated, the non-FEMA LLPT members' primary role is to provide data and input to FEMA, including commenting on the creation of levee reaches and the procedures to be used for analyzing and mapping the reaches based on local levee conditions.

In some circumstances, State agencies other than the State agency represented by the State NFIP Coordinator may be active participants in the LLPT. Their roles will vary based on the specific agency's mission and relationship to the impacted communities and levee owners.

In many situations, a USACE District office will have a history of providing support to impacted communities and levee owners. The FEMA Regional Office representative should coordinate with USACE District office staff before establishing the LLPT to discuss what role the USACE District Office staff will assume on the LLPT. Likewise, the FEMA Regional Office representative will coordinate with OFAs other than USACE in determining their role when it is appropriate for them to participate.

6.6 Local Levee Partnership Team Meetings (Figure 11, Element 300)

6.6.1 Meeting Objectives

In addition to the general Risk MAP objectives, the LLPT has the following specific objectives:

- Provide all members the opportunity to explain the unique conditions that will influence the analysis and mapping associated with the non-accredited levee system.
- Allow for discussion on the information and data obtained and the results of any analyses presented.
- Allow for comment on methods for levee reaches, analyses, and mapping within the allowable guidelines.
- Develop, if necessary, a reasonable schedule for obtaining input or additional data.

6.6.2 Meeting Timing and Format

Depending on the complexity of the levee system under consideration, the FEMA Regional Office representative and LLPT members will determine the number and format for the LLPT Meetings and other coordination activities.

The initial LLPT Meeting will take place after the stakeholder coordination, data collection, and initial data analysis have taken place. As discussed in Section 6.4 of this document, the FEMA

Project Officer and other Project Team members will use the initial data analysis to help explain alternatives to the LLPT members and get their input.

In many instances, an initial field reconnaissance will have occurred before the initial LLPT Meeting. However, as discussed in Subsection 6.3.7 of this document, this reconnaissance activity could follow the initial LLPT Meeting, depending on the local situation.

The LLPT Meetings may be held in-person, via conference call, or via the Internet. Decisions regarding where and when to hold meetings will be based on the local logistical situation, availability of members, and the complexity of the levee system being evaluated.

6.6.3 Meeting Attendees

The FEMA Regional Office representative is to assure that all LLPT members are invited to all LLPT Meetings. (See Subsection 6.5.3 of this document for a list of potential LLPT participants).

6.6.4 Meeting Messages

The message for the initial LLPT Meeting (and subsequent meetings) continues to be "Living with levees - It's a shared responsibility". The specific message to the LLPT is that FEMA recognizes that unique local levee conditions exist, and the FEMA Regional Office representative will work with the other LLPT members and use local data and input to determine how best to analyze and map hazards in levee-impacted areas. An additional message is that, while FEMA has the final decision-making authority on how the flood hazards landward of the non-accredited levee system will be analyzed and mapped, the process for reaching that decision will emphasize an interactive exchange of information and ideas among the LLPT members.

6.6.5 Pre-Meeting Activities

The following activities will occur before the initial LLPT Meeting:

- The FEMA Regional Office representative will send an invitation email to the first LLPT Meeting (and all subsequent meetings) to each LLPT member.
- The FEMA Regional Office representative will provide LLPT members with introductory briefings and training materials on the procedures for analyzing and mapping non-accredited levee systems.
- The Project Team will conduct an initial data analysis, discussed in Subsection 6.4.4 of this document, to provide an overview of alternative approaches for various levee reaches. This could include any draft maps or other results that would be helpful to communicate the impact of different approaches.
- The Project Team will develop a summary of data and information obtained during the data collection and reconnaissance efforts.

6.6.6 Meeting Activities

During the LLPT Meeting(s), the FEMA Regional Office representative will:

- Explain the LLPT Meeting objectives and the need for transparency.

- Inform the LLPT members that meeting minutes to document who attended and what happened at the meeting will be produced and made available to all stakeholders.
- Provide a summary of the background of the flood hazard mapping project.
- Provide a summary of the levee analysis and mapping process.
- Answer any questions about the levee analysis and mapping process and the briefing and training information previously provided.
- Summarize the following information:
    - Meeting messages
    - Results from the data collection efforts
    - Results from the initial data analysis, including any draft map and USACE Levee Screening Tool results
    - Possible alternative approaches for analyzing and mapping flood hazards landward of the levee system(s)

6.7 Levee Analysis and Mapping Plan (Figure 11, Element 400)

The LLPT will use the data available to select the appropriate procedure to analyze and map the flood hazards landward of the levee system(s) being considered. The initial evaluation will be an estimate of the natural valley floodplains. This information can provide an initial sense of where flooding may occur landward of the levee system. If other information is available, such as an estimate of a levee breach analysis/map, the LLPT will also use that information. Some examples of key considerations in selecting the appropriate levee analysis and mapping procedure are as follows:

- Levee system characteristics
- Data availability
- 44 CFR 65.10 deficiency type
- Length/size of the levee system and/or levee reach
- Levee crest profile versus BFEs
- Levee system performance history
- Accreditation status of levee system on current, effective NFIP map(s)
- Flooding characteristics
- Contributing drainage area
- Terrain data
- Population consequence, risk, and population information
- Community, Tribe, levee owner, and/or local project sponsor willingness to contribute data or analyses

The LLPT may discover that a restoration project for the levee system is underway through coordination with State, community, or Tribal officials; levee owners; and/or OFAs, including USACE. FEMA has not revised the regulatory requirements provided in 44 CFR 61.12 for new construction projects that have made adequate progress toward completion nor the regulatory requirements provided in 44 CFR 65.14 for decertified levee systems that are being restored to base flood hazard-reduction capability. (See Figure 11, Element 500.)

Once the LLPT has completed its deliberations, the Project Team will produce a final version of the Levee Analysis and Mapping Plan. The Plan will include the following:

- Copies of the data developed, including agendas, meeting minutes, attendance sheets, and correspondence
- Summary of the data and information collected, when they were received, type, and source
- Summary of data, documentation, and information FEMA expects to receive from stakeholders, including the recommended timeframe for delivery
- Flood hazard analysis and mapping options based on data that are already available and timeframe for when data to be collected by stakeholders is to be provided to FEMA

In addition to the Levee Analysis and Mapping Plan, FEMA will use the data and information collected to update the NLD if data collected during this phase came from sources other than the NLD. See Chapter 3 of this document for more information on reporting updates to levee data documentation and inventory. FEMA will provide the final version of the Levee Analysis and Mapping Plan and database to the levee stakeholders with whom FEMA coordinated during the data collection and stakeholder engagement process, including all LLPT members.

6.8 Additional Data Collection (Figure 11, Element 410)

In some cases, the Levee Analysis and Mapping Plan may include a summary of data FEMA expects to receive from stakeholders that may affect the reach approaches used and the recommended timeframe for delivery of the additional data. The timeframe for the community providing additional data will depend on many factors, including:

- Whether the levee system was previously provisionally accredited
- Type of data being collected
- Planned project schedule, if the levee is part of a larger watershed or countywide flood hazard mapping project
- Contractual timeframes between the FEMA Regional Office and other Project Team members (i.e., CTPs, Risk MAP providers)
- Size and complexity of the levee system.

Table 3 presents suggested ranges of timeframes for supplying additional data. Because the appropriate timeframe for supplying additional data will depend on many factors, the chosen timeframe should fit the actual project conditions, but should generally not exceed the upper limits of the listed ranges.

Table 3: Suggested Timeline for Additional Data

Data Type	Timeframe Range		Stakeholder Responsible for Data
	Previous PAL Designation	No Previous PAL Designation	
Elevation Information for the Levee Crest and Toe	Up to 2 months	Up to 6 months	Levee Owner/Community
Operations and Maintenance Plan	Up to 3 months	Up to 3 months	Levee Owner/Community
Structural Design Requirements	Up to 6 months	Up to 18 months	Levee Owner/Community
Inspection Reports	Up to 2 months	Up to 2 months	Levee Owner/Community
Evaluation of Overtopping Erosion Potential	Up to 18 months	Up to 18 months	Levee Owner/Community

6.9 System-Wide Analysis and Mapping Procedures (Figure 11, Element 610)

For non-accredited levee systems, the Project Team will combine four major components to develop the final flood hazard information reflected on the FIRM:

1. A system-wide Zone D area developed using the Natural Valley Procedure
2. A system-wide SFHA based on an interior drainage analysis developed assuming the levee system remains in place
3. Merged SFHAs determined from the appropriate levee reach procedures detailed in Section 6.10 of this document
4. An SFHA developed for the flooding source side of the levee system assuming the levee system remains in place

A registered P.E. must sign and seal all engineering data developed for each procedure, and this will satisfy the certification requirements of 44 CFR 65.2 and 44 CFR 65.10(e). If required, structural, operations, maintenance, and overtopping analysis data submitted by a levee owner or community will be reviewed for completeness.

6.9.1 Natural Valley Zone D

FEMA will represent the uncertainty of the hazards associated with the non-accredited levee system(s) through use of the Zone D designation. FEMA uses the Zone D designation on a FIRM to identify areas of undetermined, but possible, flood hazards. In the future, FEMA may define and adopt another zone designation through the regulatory process.

The Project Team will depict any area within the Natural Valley footprint that is not an SFHA as Zone D on the FIRM. The Project Team will use the Zone D designation to identify the area of

possible base flood hazard that exists because the levee system is non-accredited. The Project Team will determine this area using the Natural Valley Procedure (discussed in Section 6.12 of this document). This is similar to the process used to determine the Zone X (shaded) areas for accredited levee systems.

The Zone D designation is used for non-accredited systems instead of the Zone X (shaded) designation used for accredited levee systems because the flood hazard potential is greater and more uncertain than with accredited levee systems.

If levee systems exist on both sides of a flooding source, or multiple systems that overlap exist, the Project Team will determine the extents of the Zone D area for each system independently, assuming the other systems remain in place.

6.9.2 Interior Drainage Analysis

The Project Team will evaluate the adequacy of the interior drainage systems and map an SFHA for the base flood where applicable. Interior drainage associated with levee systems usually includes storage areas, gravity outlets, pumping stations, and other residual flooding, or a combination thereof. In performing the interior drainage analyses, the Project Team will assume that all sections of the levee and associated structures will remain intact in their current condition.

Judgment will be required to determine if the interior drainage systems need to be analyzed. The FEMA Regional Office representative will decide how to analyze and map interior drainage after consultation with the community officials, levee owner(s), and/or local project sponsor(s), and the Project Team. If the potential for mappable flooding exists on the landward side of the levee system due to interior flooding, the Project Team will perform an interior drainage analysis. If the Project Team used the Natural Valley Procedure (discussed in Section 6.12 of this document or Structural-Based Inundation Procedure (discussed in Section 6.13 of this document) for the entire system, no additional interior drainage analysis may be required if those flooding conditions would result in flooding more extensive than the interior drainage analysis.

USACE Engineer Manual (EM) EM 1110-2-1413, Engineering and Design - Hydrologic Analysis of Interior Drainage Areas (or subsequent updates on this topic), provides guidance and criteria for performing an interior drainage analysis for levee systems, including joint probability analyses.

6.10 Levee Reach Analysis and Mapping Procedures (Figure 11, Element 620)

In addition to the system-wide hazard mapping associated with the Natural Valley Procedure, the levee system may be divided into reaches (see Figure 14) to develop additional SFHA. A levee reach is defined as any continuous length of a levee system to which a single technical procedure may be applied. A levee reach has no minimum or maximum length requirement. Individual reaches can be analyzed using the following procedures:

- Natural Valley Procedure
- Structural-Based Inundation Procedure
- Overtopping Procedure
- Freeboard Deficient Procedure
- Sound Reach Procedure

The Project Team may apply each procedure, except for the Sound Reach Procedure, at both the reach and system levels. The Sound Reach Procedure cannot be used because a levee system of sound reaches would be considered an accredited levee. The Project Team will complete the analysis of a single reach with all other levee reaches intact.

The Project Team will merge the flood hazard information that results from the analyses of the individual levee reaches within the system along with any interior drainage flood hazards. The result will be a composite SFHA delineation landward of the levee system. As mentioned in Subsection 6.9.2 of this document, the Project Team will designate any area within the Natural Valley footprint that is not SFHA as Zone D.

No stakeholder data or documentation is required for applying the Natural Valley Procedure. In situations where FEMA is not provided with the data/documentation required for use in the reach analysis procedures, the Project Team will apply the Natural Valley Procedure at the reach or system level.

The Project Team will apply the reach analysis procedures and corresponding stakeholder data requirements shown in Table 4 when analyzing non-accredited levee systems. It is the responsibility of the community, Tribe, levee owner, and/or local project sponsor to provide the data/documentation to support the standards in Table 4 for the levee reach if that approach is to be applied.

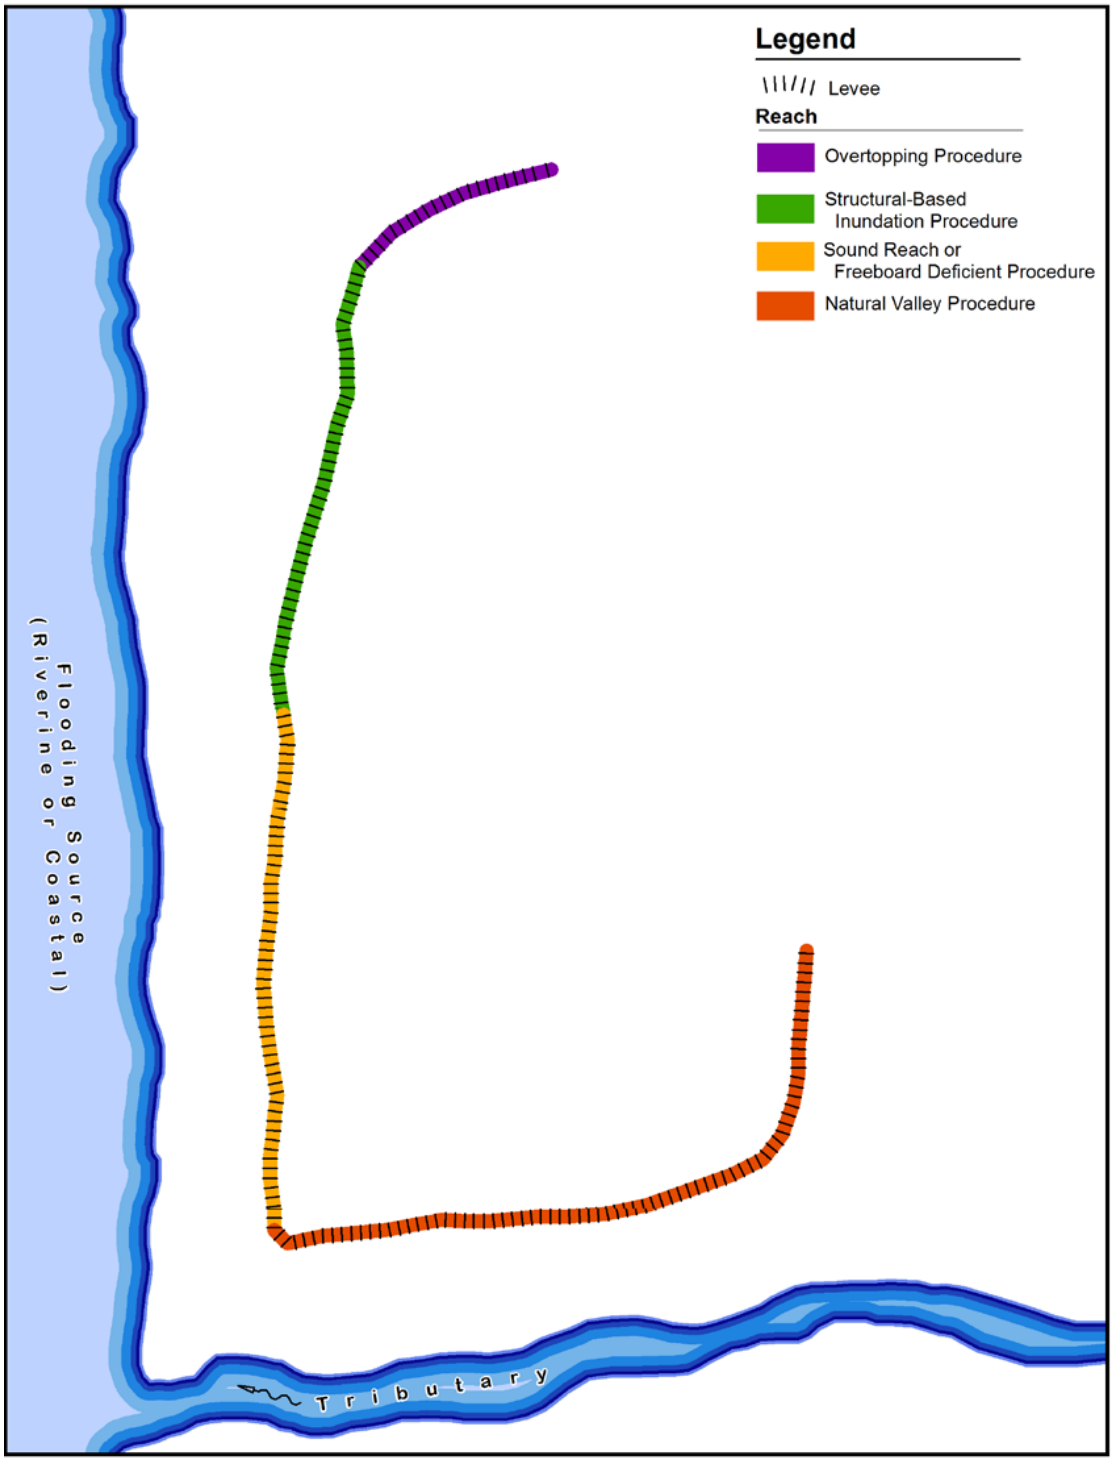

Figure 14: Example Segmentation of a Levee System

Table 4: Summary of Stakeholder Data Standards for Reach Analysis Procedures

Data Element	Applicable Portion of CFR	Reach Analysis Procedures				
		Sound	Freeboard Deficient	Overtopping Approach	Structural Based Inundation	Natural Valley
Elevation Information for Levee Crest and Toe	N/A	Required	Required	Required	Required	N/A
BFE + Freeboard Less than Levee Crest	44 CFR 65.10(b)(1)	Required	N/A	N/A	N/A	N/A
BFE Less than Levee Crest	N/A	Required	Required	N/A	N/A	N/A
O&M Plan	44 CFR 65.10(c)	Required	Required	Required	Recommended	N/A
Structural Design Standards	44 CFR 65.10(b)(2) – 44 CFR 65.10(b)(7)	Required	Required	Required	N/A	N/A
Inspection Reports	44 CFR 65.10(c)(2)(iv)	Required	Required	Required	Recommended	N/A
Evaluation of Overtopping Erosion Potential	N/A	N/A	N/A	Required	N/A	N/A

Surveyed elevation data for the levee crest and levee toe, if required, must meet FEMA standards. All engineering data submitted for each of the procedures must be signed and sealed by a registered P.E. The registered P.E.'s signature and seal have the same meaning as the certification required by the NFIP regulations as cited at 44 CFR 65.2 and 44 CFR 65.10(e). Review of this data shall be performed as described in Section 4.3 of this document.

FEMA will not fund any efforts solely related to certifying data for levee accreditation or making determinations of the levee's structural conditions.

6.11 Natural Valley Procedure (Figure 11, Element 620)

The Natural Valley Procedure can be applied to all non-accredited levee system reaches to determine the SFHA and to determine the Zone D area. Factors that the Project Team will need to consider when determining whether to use the Natural Valley Procedure to determine the SFHA for a reach are provided below.

6.11.1 Hydraulic Significance of the Levee Reach

In some cases, a levee reach is so significantly overtopped during the peak of the base flood event that the existence of the levee does not have a noticeable effect on the water-surface elevation (WSEL). Techniques and items to consider for this situation are included in Subsection 6.12.5.

6.11.2 Availability of Data

If no data are available to support the other procedures, the Project Team will apply the Natural Valley Procedure. In some locations, the SFHA shown on the effective FIRM for the flooding source side of the non-accredited levee system is based on a Base Level study and, therefore, the SFHA is designated as Zone A or Zone V. In these locations, FEMA will evaluate the need for new modeling of the flooding source for performing the Natural Valley Procedure. If the need does not exist, the SFHA shown for the effective flooding source mapping will continue to be designated Zone A. If the need exists, the SFHA for the flooding source may be designated Zone A or Zone AE, depending on the modeling method(s) used.

6.11.3 Needs of the Community

Because of the limited data requirements and resources required to analyze a levee reach using the Natural Valley Procedure, a community may prefer to use this method. Therefore, the community may also request that FEMA use the Natural Valley Procedure.

The Project Team will model and map the natural valley floodplain landward of the non-accredited levee systems as an SFHA, except when additional analysis indicates an alternate treatment. The Project Team will only depict the natural valley floodplain landward of non-accredited levee systems as Zone D when the Freeboard Deficient, Sound Reach, Overtopping, or Structural-Based Inundation Procedure is implemented.

6.11.4 Data or Documentation Requirements

No data or documentation are required from community officials, levee owners, and/or local project sponsors to proceed with the Natural Valley Procedure.

6.11.5 Technical Procedures

Using the Natural Valley Procedure, the Project Team will model the flooding along the levee reach by allowing the discharge to flow freely on either side of the levee for the entire levee reach. The levee will not impede conveyance in the model. For riverine levee reaches , topographic features of the levee should be in-place in the model if possible, but not allowed to obstruct lateral flow (see Figure 15). Figure 16 shows an example of an SFHA delineation when the Natural Valley Procedure is applied to a reach of a non-accredited levee system.

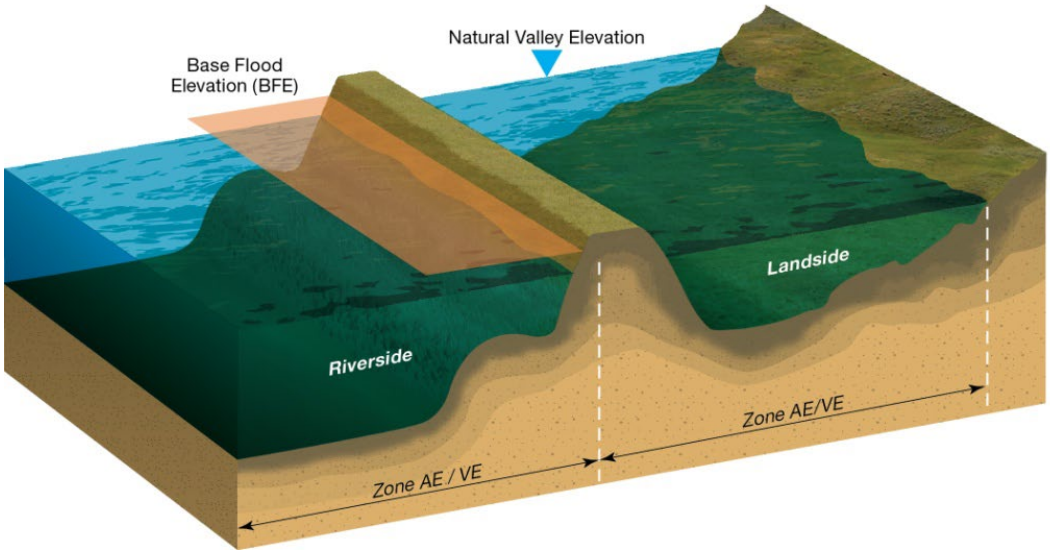

Figure 15: Natural Valley Cross-Section View

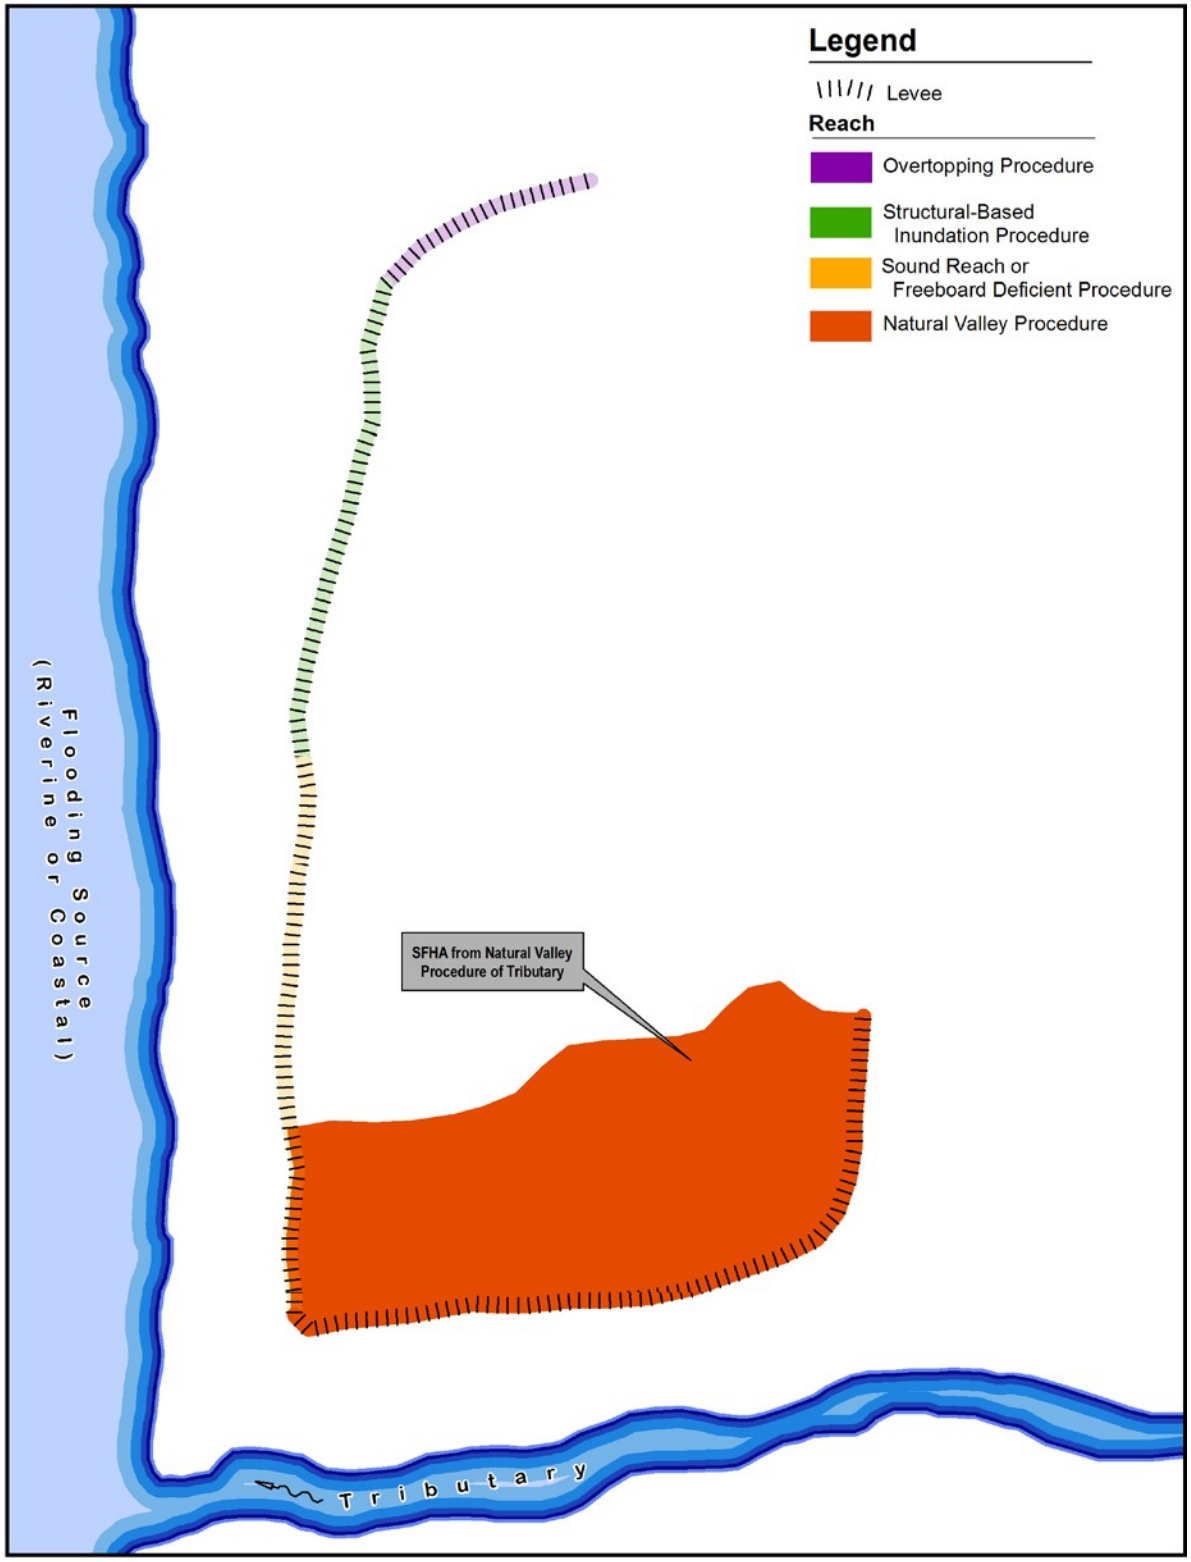

Figure 16: SFHA Delineation Using Natural Valley Procedure

6.11.5.1 Testing the Hydraulic Significance of the Levee Reach for Riverine Levees

Characteristics of the levee reach that may indicate the levee is not hydraulically significant include:

- Levee/floodwall is fully submerged, and landward conveyance is in the direction of the riverflow.
- Lateral exchange of flow across a levee that is overtopped is insignificant or does not exist because the water level on the landside of the levee equalizes with the flooding source.
- Height of the levee/floodwall is low compared to the WSEL over the crest of the levee/floodwall for the majority of the length of the levee/floodwall, as outlined in Section 6.13.

6.11.5.2 Modeling the Natural Valley Procedure on Levees Subject to Riverine or Lacustrine Flood Forces

Using the Natural Valley Procedure, the Project Team will model the riverine levee reaches by leaving the topographic features of the levee in the model, if possible, but allowing the discharge to flow on either side of the levee, as shown in Figure 15. The levee will be modeled as not impeding conveyance.

6.11.6 Coastal Levee Situations

Coastal non-accredited levees subject to flood forces will be intact within the storm surge model setup to determine peak storm-surge elevations seaward of the levees. In these situations, the Project Team will consider how the levee system will influence wave propagation. The team will then assume a steady-state condition landward of the levee and will extend the BFE landward of the non-accredited levee until it intersects the ground elevation (or the levee on the opposite side, in the case of a ring levee). The Project Team will evaluate the potential of waves forming again landward of the levee. The Project Team may apply a similar procedure when a detailed storm surge model is not available.

6.11.7 Natural Valley Letter of Acceptance

A community's agreement for using the Natural Valley Procedure for the levee system(s) may be documented in a "Natural Valley Letter of Acceptance." The FEMA Project Officer will provide the template for the Natural Valley Letter of Acceptance. In preparing this letter, the Project Team is to follow the appropriate concurrence process, as determined by the FEMA Project Officer, so that the letter is properly reviewed and approved.

6.12 Structural-Based Inundation Procedure (Figure 11, Element 620)

In some instances, levee systems have reaches with either known structural deficiencies or a lack of data to support one of the other procedures. For levee reaches that fall into this category, FEMA developed the Structural-Based Inundation Procedure to identify the limits of the base flood that may result from the potential levee failure. This procedure relies on the modeling of levee breaches along the levee reach.

Predicting the exact location of a future breach to a levee or floodwall is not possible. The Structural-Based Inundation Procedure, therefore, does not predict the probability of failure at any breach location nor does it provide a specific determination or evaluation of the overall levee system performance or require a determination of the likely failure mechanism. Implementation of the procedure instead results in the development of an SFHA based on the flood hazard due to potential breaches along a particular levee reach during a base flood event.

6.12.1 Data Requirements

The only mandatory data required are accurate top-of-levee and toe-of-levee elevations. However, in certain circumstances, FEMA may require the following information to apply the Structural-Based Inundation Procedure, which should follow the standards of 44 CFR 65.10:

- O&M Plan. Details of the O&M Plan standard are provided in 44 CFR 65.10(c).
- Structural design standards. Structural design should meet minimum design standards including data regarding closures in 44 CFR 65.10(b)(2), embankment protection in 44 CFR 65.10(b)(3), embankment and foundation stability in 44 CFR 65.10(b)(4), settlement in 44 CFR 65.10(b)(5), and any other design standards in 44 CFR 65.10(b)(6).
- Inspection reports. The standard for documentation of inspection is provided in 44 CFR 65.10(c)(1)(iii) and 44 CFR 65.10(c)(2)(iv).

No freeboard or WSEL requirements apply to the Structural-Based Inundation Procedure. Therefore, the Project Team will apply this procedure when the levee crest is lower than the base flood level, but high enough to impede flow.

6.12.2 Technical Procedures

Methods to identify possible locations of system breaches, modes of failure, geometry, failure triggers, and failure duration for use in mapping the base flood resulting from the breaches are described in Subsections 6.13.2.1 through 6.13.2.4. Given the number and nature of assumptions inherent in this procedure, FEMA will allow flexibility in the use of the Structural-Based Inundation Procedure to enable the use of engineering judgment. In rural settings, where levee systems reduce the hazard to primarily agricultural lands, yet the levees are hydraulically significant, simplification of the approach may be warranted to limit analysis costs that would not result in significantly different flood hazard mapping.

6.12.2.1 Determination of Modeled Breach Locations

The locations of possible levee breaches could be determined using the method described below.

- Select initial breach locations for each levee reach, one representing a breach location near the downstream end of the levee reach and another near the upstream end of the levee reach.
- Determine the hydrograph through each breach, also known as “the breach hydrograph”, and independently analyze the hazard for the base flood landward of the levee for each breach.
- Combine the resulting flood hazard boundary delineations into a composite SFHA delineation.

- Make an initial judgment, through examination of the terrain landward of the levee and/or preliminary modeling results, on whether the selected breach locations will result in a reasonable identification of the flood hazard. The flood hazard will be considered to have been reasonably identified when all potential storage areas and flow paths that can be reached by breach flows are reflected in the flood hazard mapping (as Zone AE, Zone AH, and/or Zone AO). The final SFHA on the landside of a reach using the Structural-Based Inundation Procedure must reflect the fact that a breach may occur at any location along the reach.
- Add additional breach locations to the initial locations if additional breaches can change the flood elevations or the extent of the composite flood hazard area significantly.

The assigned Project Team member generally will place the breach locations to capture the full flood hazard on the landside of the levee. The assigned team member will base exact locations on breach potential indicators, such as greatest overtopping depth, past breach locations, encroachment or known seepage locations, or changes in levee material or shape. For coastal areas, the assigned team member will also consider levee exposure to waves and potential wave runup.

6.12.2.2 Time of Breach Initiation

The time that a breach is assumed to be triggered will influence the peak flow and volume through the breach. For an overtopping breach, the assigned Project Team member will conduct a sensitivity analysis to estimate the breach initiation time that produces the most reasonable SFHA. The team member will choose the time that produces the most reasonable case using sound engineering judgment. For an internal failure analysis, the breach failure should initiate at the peak flood stage, unless information that suggests a different breach initiation time is appropriate.

Another option for the assigned Project Team member to consider when determining at what point to initiate the breach is the point in time when the water rises to an elevation at which the levee fails to meet all standard engineering criteria. This will be before peak stage in most cases.

6.12.2.3 Breach Shape

A rectangular shape extending vertically from the levee crest to the riverside toe elevation will be adequate to describe the breach shape, unless additional analysis determines breach side slopes are important and necessary for accurate modeling of the breach. The minimum breach width will be 100 feet for clay levees and 500 feet for sand levees. These minimum accepted breach widths are based on a qualitative review of the historic breach width information available. However, levee attributes and sound engineering practice should support the breach width chosen.

Based on an evaluation of historic breach widths, typically breach widths should be larger than these minimum accepted values. The breach width estimation may consider levee embankment height, levee material, crest width, depth and duration of overtopping, longitudinal velocity, area impacted by the levee, distance from the flooding source, and duration of flooding event. The method to estimate breach width will be based on sound engineering judgment, adjusted by comparing to historical documented levee breaches where available.

The assigned Project Team member will provide adequate justification for the choice of breach parameters. Unless other information is available, the team member will assume that the breach will extend vertically to the bottom of the levee.

6.12.2.4 Empirical Methods for Estimating Breach Shape

Dam Breach Equations

Several authors have developed empirical equations to estimate breach size, shape, and failure time for dam breaches. The equations are based on examination of historical data for dam breaches. Levee failures generally end with much wider breach bottom widths than dams, relative to the height of the levee/dam. The wide breach width may be caused in part by the erosive sheer force of floodflow parallel to levees and in part by the tendency for the hydraulic head over the breach to remain elevated for a longer period. Dam breach parameter empirical equations may be applicable to levees in some situations, but justification for their use will be needed if they are chosen for the levee breach width computation.

Historical Levee Breach Information

If available, historic levee breach information is an important tool in determining breach shape and development time. No nationwide compendium of historic breach information is available, but the assigned Project Team member performing the analysis will search for historical breach information.

Physically Based Models for Estimating Breach Shape

Where appropriate information is available to do so, the Project Team may use physically based breaching models. These models can be based on erodibility of the levee and levee foundation, levee, and levee foundation soil type, levee vegetative cover, flood stage, and flood duration.

When floodwalls fail, it is typically a partial breach as one or more sections (i.e., monolith) formed during the floodwall construction are forced apart by escaping water. When conducting a breach analysis on a floodwall, the assigned Project Team member will need to determine the number of sections that might fail as the breach width is based on the particular structure, available documentation, and engineering judgment. The minimum expected breach width for a floodwall is one section (i.e., monolith).

Development Time

Typically, the Project Team member can set the time for breach formation (the time from breach initiation to the time full breach width is realized) to zero to simplify the analysis. If is the assigned team member determines that the breach formation time would have a significant impact on the breach hydrograph, the assigned member may need to consider this variable in the analysis.

Sensitivity Analysis

A Project Team will conduct sensitivity analysis to evaluate the effects that varying the levee breach width and failure initiation time will have on the resulting flood hazards, within reasonable limits. This sensitivity analysis will include widening and narrowing the levee breach width within reasonable bounds and investigating the impacts of different breach initiation times. As the parameters are varied, the assigned team member will note the impacts to the peak discharge,

volume through the breach, and the SFHA. In general, the final parameters chosen by the assigned team member will represent the most reasonable flood hazard that result from the parameters evaluated.

To test the impact of failure initiation time, the assigned Project Team member will conduct a calculation initiating the breach at the point of overtopping of the levee on the ascending or rising limb of the flood hydrograph. Also, the assigned team member will perform a breach calculation at the time to peak flood stage, but not greater than 2 hours after overtopping begins. The team member may extend the duration of overtopping if technical calculations, prepared by a registered P.E., are provided by the community, Tribe, levee owner, and/or local project sponsor to indicate that the levee can withstand additional overtopping without failure. The assigned team member will compare breach flows or hydrographs and will use the one that produces the most reasonable flood hazard landward of the levee.

For coastal levees, the sensitivity analysis will include testing related to the duration of a storm surge hydrograph.

6.12.3 Mapping Breach Analysis Results

The SFHA shown on the FIRM will be based on a composite of the base flood hazard developed at each breach location. (See Figure 17.) Figure 18 shows an example of an SFHA delineation when the Structural-Based Inundation Procedure is applied to a reach of a non-accredited levee system. The Project Team will assure that the final SFHA reflects the fact that a breach may occur at any location along the Structural-Based Inundation levee reach. The modeled breach locations should not be apparent in the final SFHA delineation or BFEs.

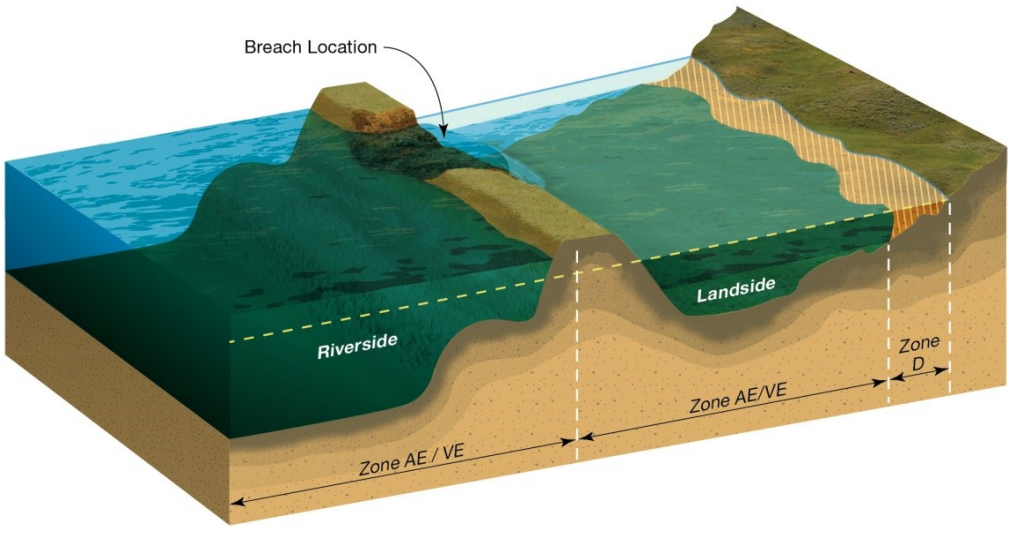

Figure 17: Structural-Based Inundation Cross-Section View

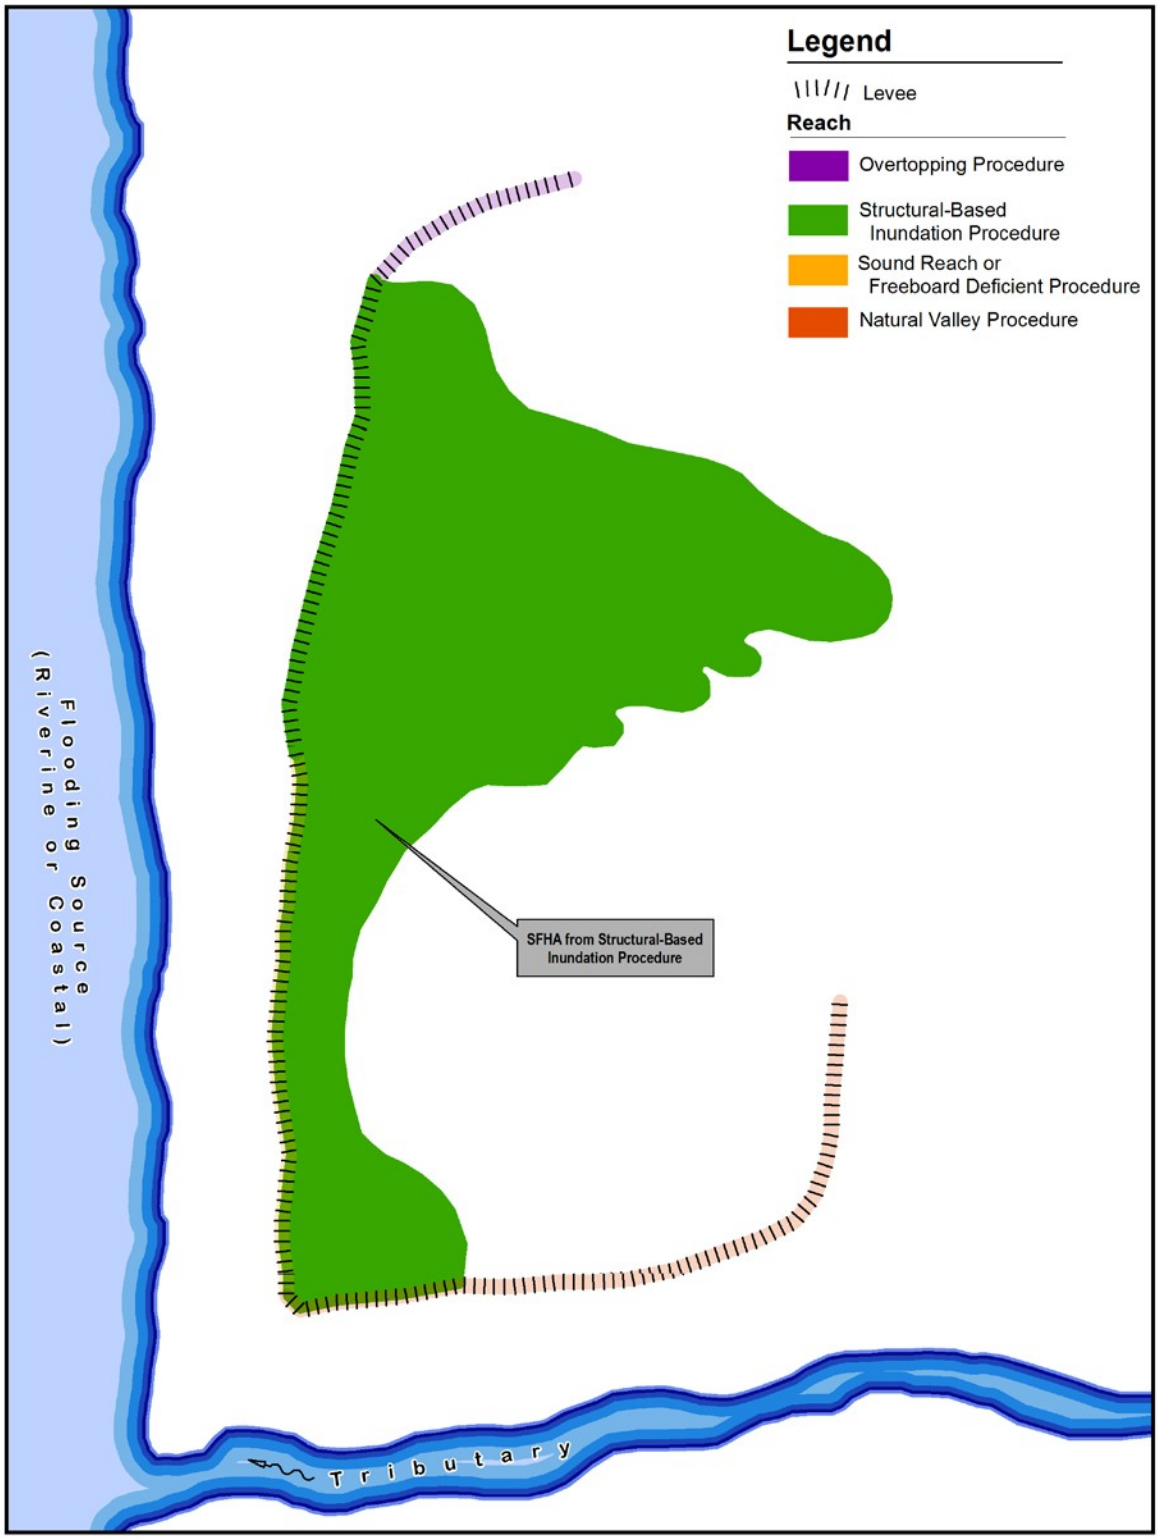

Figure 18: SFHA Delineation Using Structural-Based Inundation Procedure

6.13 Overtopping Procedure (Figure 11, Element 620)

In some instances, levee systems have locations that have been specifically armored to sustain overtopping flows or the rate of overtopping flow is sufficiently small or of sufficiently short duration that the system would not fail during the base flood. The Overtopping Procedure can be applied when the BFE is above the levee crest for a reach, but it can be demonstrated that the base flood event will not cause structural failure and the levee reach meets all standards of 44 CFR 65.10 except 44 CFR 65.10(b)(1).

6.13.1 Data Requirements

For the Overtopping Procedure to be used for a reach, the community, levee owner, or local levee sponsor must submit an analysis, signed, and sealed by a registered P.E., to FEMA. This analysis must indicate that no appreciable erosion of the levee crest, toe, embankment, or foundation occurs during the overtopping of the base flood event because of either currents or waves. The analysis must also demonstrate that the anticipated erosion will not result in structural failure. Failure is defined as breach of the levee, directly or indirectly, through loss of embankment material due to erosive forces, the reduction of the seepage path, or piping and subsequent instability. In addition, the community, levee owner, or local levee sponsor must submit documentation to meet the following standards from 44 CFR 65.10 to FEMA:

- O&M Plan. Details of the O&M plan standard are provided in 44 CFR 65.10(c).
- Structural design standards. Structural design must meet minimum design standards, including data regarding closures in 44 CFR 65(b)(2), embankment protection in 44 CFR 65.10(b)(3), embankment and foundation stability in 44 CFR 65.10(b)(4), settlement in 44 CFR 65.10(b)(5), interior drainage in 44 CFR 65.10(b)(6), and any other design standards as detailed in 44 CFR 65.10(b)(7).
- The structural design documentation should also include a discussion if the failure of an adjacent levee could affect the structural integrity reach if that adjacent levee reach is not categorized as Sound or Freeboard Deficient.
- Inspection reports. The standard for documentation of inspection is provided in 44 CFR 65.10(c)(1)(iii) and 44 CFR 65.10(c)(2)(iv).
- Elevation information for the levee crest and toe.
- Certified as-built drawings

All items must be signed and sealed by a registered P.E.

In addition to the standards detailed in 44 CFR 65.10, more expansive structural documentation as well as O&M documentation will be required for these reaches to certify the overtopping analysis. These are detailed further in the subsections below.

6.13.1.1 Loading Conditions Used for Evaluation

For the loading conditions used for evaluation, the certifying P.E. will use the base flood event plus a factor of safety, such as an elevation freeboard, that takes into account uncertainty in the data. The factor of safety used will depend on the levee reach and engineering judgment. For example, the factor of safety will vary when unique tie-in conditions exist, or control structures are

present. Because of the uncertainty in depth and duration of the overtopping flows, a factor of safety will typically be applied when considering the structural stability of the levee reach.

6.13.1.2 Armored Surfacing

Based on the certified engineering analysis submitted, a community, levee owner, and/or local project sponsor may be able to demonstrate that armoring is not required for a levee reach to fall within this scenario. However, in most cases, armoring will be expected. Some of the reasons for armored surfacing include:

- Some indication that flow along the levee reach may cause some erosion that will initiate levee breaching
- A lack of proper and continuous maintenance that would result in a non-continuous, non-uniform surface, including the lack of irrigation, fertilization, and annual inspections
- Concerns about localized irregularities, which lead to flow anomalies, because available survey data may not be indicative of localized conditions along the levee reach
- Local conditions, on the landside of the levee, include the presence of dips, depressions, or protrusions (including trees, posts, or other surface anomalies)
- Traffic rutting along the levee crest that induces non-uniform crest conditions, in terms of both levee profile and structural condition
- Difficulty in establishing and properly maintaining a dense and continuous grass cover (in semi-arid and arid regions)
- Debris carried by floodflow that could induce damage to the protective surfacing
- A small amount of damage to a dry or cracked embankment, leading to a catastrophic failure during overtopping
- Risk reduction in high-impact areas

The items below may be considered when determining the viability of an armored surface:

- History of Events. Flood levels, overtopping locations, damage assessments, and maintenance records can be considered to evaluate the damage that occurred during past overtopping events, especially if depth and duration can be established and evidence shows minor to no damage occurred. If the levee has experienced piping or sand boils, the stability of the levee should be questioned. These data will not be used to change the accreditation determination made at the beginning of the levee analysis and mapping process.
- Potential freeboard loss due to subsidence or localized settlement. Frequent, accurate surveys are critical so that an adequate safety factor is maintained in an area where long-term settlement and regional subsidence are common.
- Overtopping height and overtopping flow rate (cubic feet per second). Velocity and tractive-force calculations are key considerations to assess erosion potential.
- Overtopping duration. Levee design discharge or stage hydrographs indicating minutes, hours, or days of anticipated overtopping are especially critical for grass-covered levees.

- Uplift potential and maximum induced shear stress along the interface between the armored surfacing and the overtopping flow. Adequacy of the selected armoring scheme must be demonstrated for given site conditions.
- Resiliency of levee material. Granular and sandy soils will require surface armoring for small rates and depths of flow.
- Flow concentration potential. Surface discontinuities and irregularities can lead to irregular hydraulic flow patterns. Armoring is to be provided if gullies, tire tracks, access roads, fences, utility poles, animal burrows, cattle paths, roads, bike trails, or other conditions may exist that will concentrate flow. For grass-lined levees, the downstream slope can be evaluated to determine if it is uniform from crest to toe, with no interruptions or irregularities such as dips, depressions, or protrusions (e.g., trees, posts, or other surface anomalies).
- Effect of debris on flow patterns. Armored reaches can be subject to damage from flood-borne debris.
- Levee toe protection. This is especially required at the location of eddies, groins, and hydraulic jumps. The depth and thickness of toe protection need to be considered.
- Levee armoring alternatives. Alternatives include soil cement, articulated concrete blocks, roller-compacted concrete, gabions, geocells, and rock chutes. Each alternative will have placement thickness recommendations and associated components/feature design considerations (e.g., tieback levees, sub-drainage, anchoring requirement).
- Wind and wave action. The impact of breaking waves over the levee should be evaluated.
- Cavitation potential. How overtopping flows will affect armored surfacing should be evaluated.
- Levee height. Low levees may be more tolerant to overtopping.
- Interior side slopes. Flatter slopes (i.e., > 4H: 1V) are more tolerant. This is especially important for grass-covered levees.
- Inspections. Inspection frequency is especially important for grass-covered levees or after historical events where overtopping occurs, or the levees have been stressed.
- Validity of the O&M Plan. The O&M Plan should provide confidence in emergency planning that minimizes the effects of overtopping, including the impact at overtopping location(s) and interior drainage.
- Filter capability and free-draining bedding. Filter materials should be protected from high rates of flow.

6.13.1.3 Additional Considerations for Levees Subject to Coastal Flood Forces

A levee reach subject to coastal flood forces will need to include adequate embankment protection, foundation, and embankment stability. The levee reach will need to be designed, constructed, operated, and maintained to resist wave effects (potentially including wave overtopping and storm surcharge to resist erosion) and prevent flooding of interior areas landward of the levee crest.

For levee reaches subject to coastal flood forces with minimal freeboard, armored surfacing will need to be considered on both the seaward side and landsides of the coastal levee, including the crest, to ensure that the levee reach can withstand the wave forces to which the levee is subjected. Further discussion about armoring coastal levees is presented in USACE CERC-89-15, Criteria for Evaluating Coastal Flood Protection Structures.

6.13.2 Technical Procedures

If the appropriate data are provided as detailed in Subsection 6.14.1, the assigned Project Team member will route the flooding source hydrograph over the levee reach with the levee remaining intact. The assigned team member will then model the flooding landward of the levee system to determine the SFHA. (See Figure 19.) Figure 20 shows an example of an SFHA delineation when the Overtopping Procedure is applied to a reach of a non-accredited levee system.

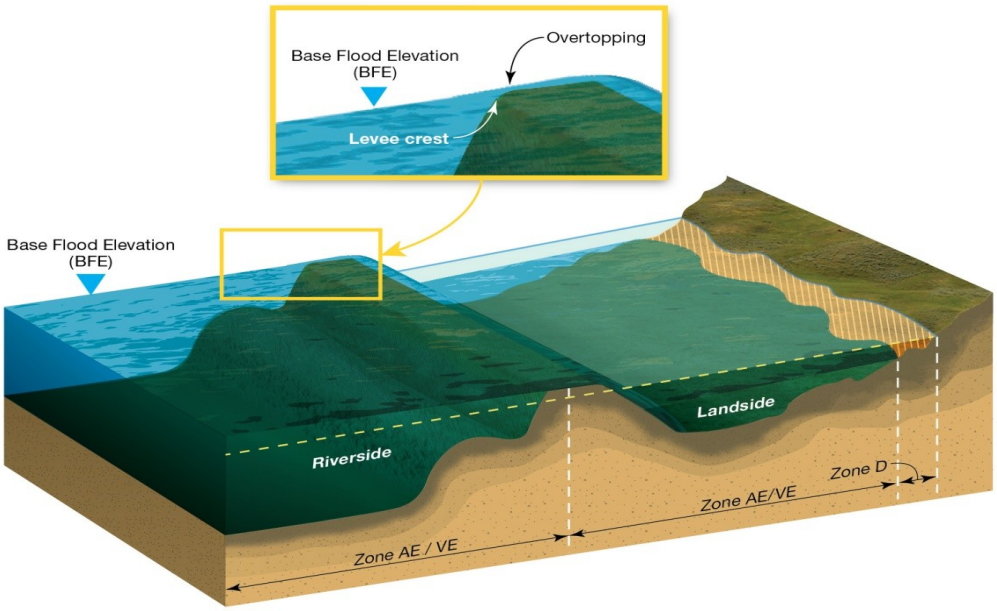

Figure 19: Overtopping Cross-Section View

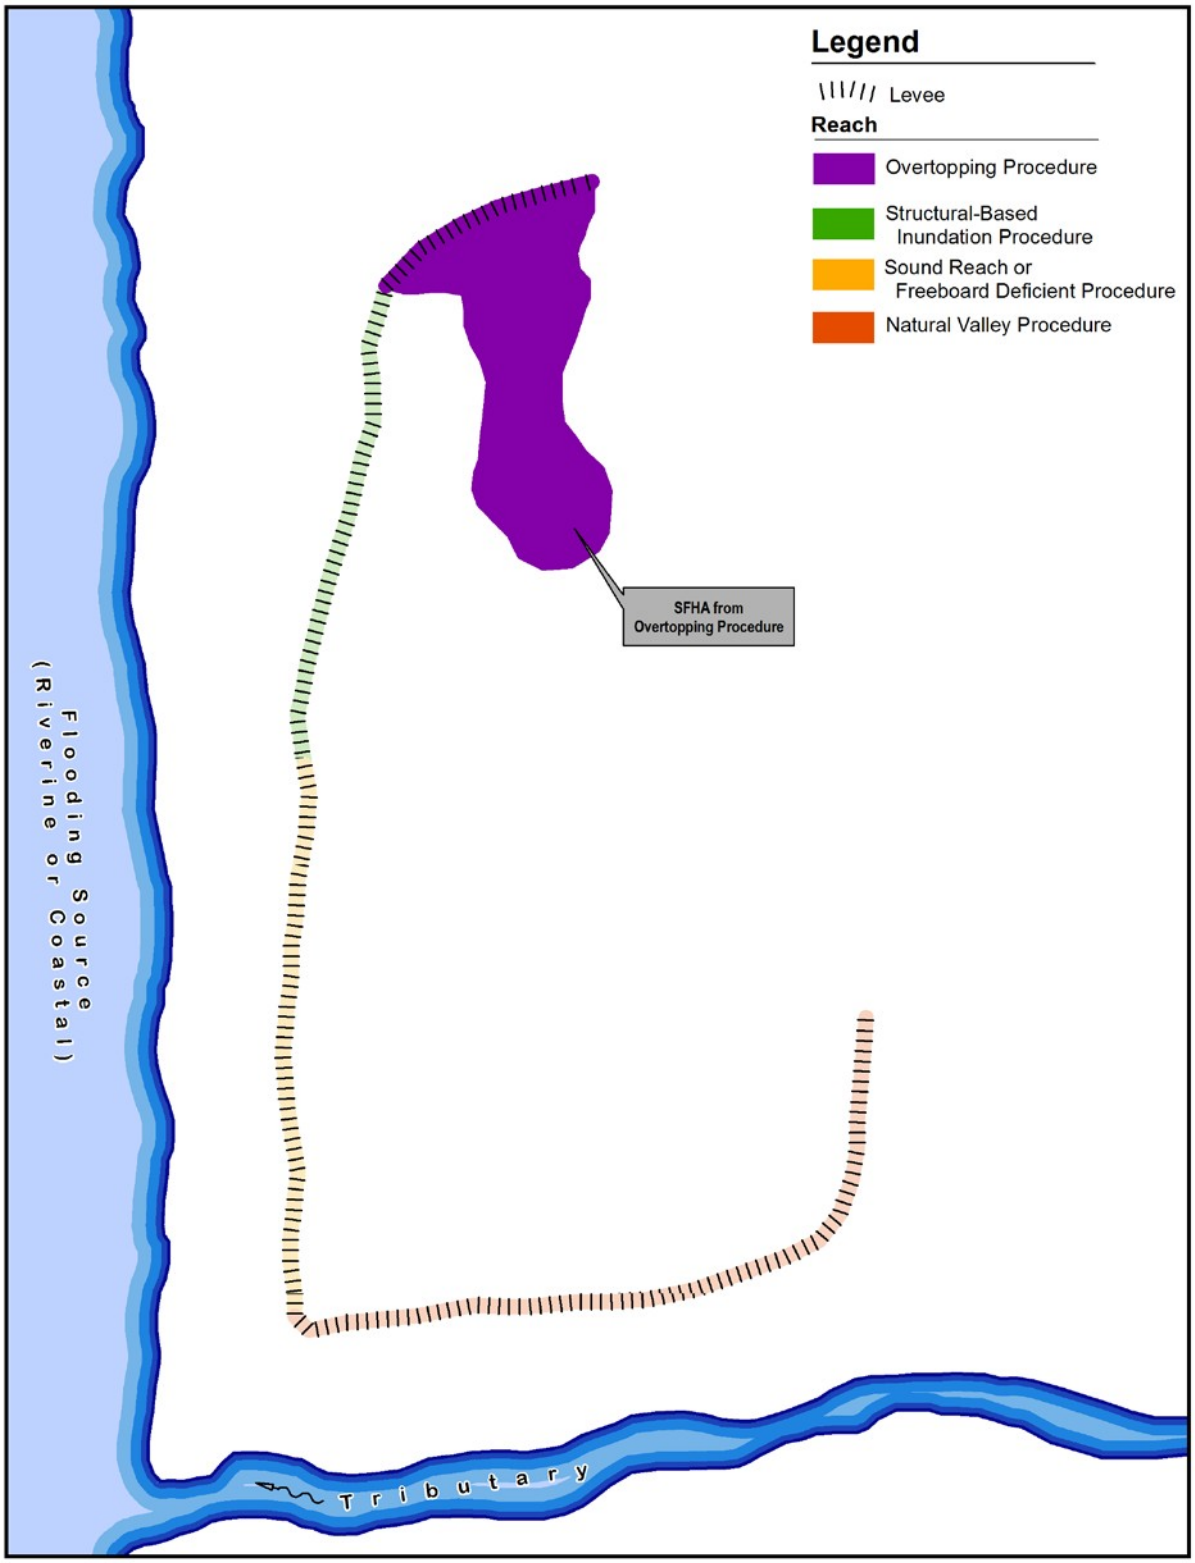

Figure 20: SFHA Delineation Using Overtopping Procedure

6.14 Freeboard Deficient Procedures (Figure 11, Element 620)

The Freeboard Deficient Procedure can be applied to reaches where the levee system meets the structural standards of 44 CFR 65.10, lacks adequate freeboard, and has a documented O&M Plan.

6.14.1 Data Requirements

To designate a levee reach as a Freeboard Deficient levee reach, the community, levee owner, or local levee sponsor must submit documentation to meet the following standards from 44 CFR 65.10 to FEMA:

- The top of the levee crest and closure structures along the entire reach must be above the BFE.
- O&M Plan. Details of the O&M Plan standard are provided in 44 CFR 65.10(c).
- Structural design standards. Structural design must meet minimum design standards, including data regarding closures in 44 CFR 65(b)(2), embankment protection in 44 CFR 65.10(b)(3), embankment and foundation stability in 44 CFR 65.10(b)(4), settlement in 44 CFR 65.10(b)(5), interior drainage in 44 CFR 65.10(b)(6), and any other design standards as detailed in 44 CFR 65.10(b)(7).
- The structural design documentation should also include a discussion of whether the failure of an adjacent levee could affect the structural integrity reach if that adjacent levee reach is not categorized as a Sound Reach or Freeboard Deficient levee reach.
- Inspection reports. The standard for documentation of inspection is provided in 44 CFR 65.10(c)(1)(iii) and 44 CFR 65.10(c)(2)(iv).
- Elevation information for the levee crest and toe.
-
- Certified As-built drawings.

All items must be signed and sealed by a registered P.E.

FEMA will review the submittal in accordance with the appropriate sections of Chapter 4 of this document.

6.14.2 Technical Procedures

No reach-specific modeling is required for a reach evaluated using the Freeboard Deficient Procedure, but the Project Team will map the system-wide Zone D area landward of the levee system for these reaches. (See Figure 21.) The SFHAs from the system-wide interior drainage analysis and/or adjacent levee reaches where different procedures have been applied may still be present on the landside of the levee with Freeboard Deficient levee reaches. This will depend on the presence of interior ponding areas and other terrain features on the landside of the levee.

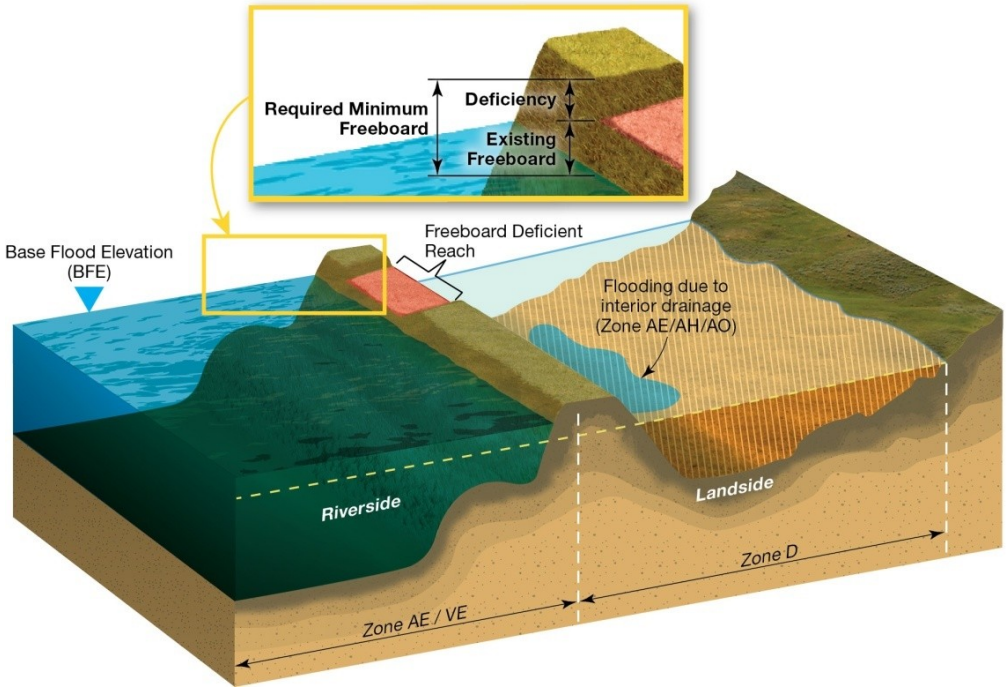

Figure 21: Freeboard Deficient Cross-Section View

6.15 Sound Reach Procedure (Figure 11, Element 620)

A Sound Reach is a levee reach that has been designed, constructed, and maintained, in accordance with sound engineering practices, to withstand and reduce the flood hazards posed by a base flood even if the entire system does not.

6.15.1 Data Requirements

Sound Reaches are part of a levee system that cannot meet accreditation requirements. Because they are only a component of a levee system, they cannot be accredited as a hydraulically independent system.

To designate a reach as sound, the community, levee owner, or local levee sponsor must submit technical data to FEMA to demonstrate that the levee reach will withstand the forces of the 1-percent- annual-chance flood event, and reasonably account for uncertainty. To accomplish this, documentation to meet the following standards from 44 CFR 65.10 must be submitted to FEMA:

- Freeboard. The levee reach must meet the minimum freeboard standards in 44 CFR 65.10(b)(1).
- O&M Plan. Details of the O&M Plan standard are provided in 44 CFR 65.10(c).
- Structural design standards. Structural design must meet minimum design standards, including data regarding closures in 44 CFR 65(b)(2), embankment protection in 44 CFR 65.10(b)(3), embankment and foundation stability in 44 CFR 65.10(b)(4), settlement in 44 CFR 65.10(b)(5), interior drainage in 44 CFR 65.10(b)(6), and any other design standards as detailed in 44 CFR 65.10(b)(7).

The structural design documentation should also include a discussion if the failure of an adjacent levee could affect the structural integrity reach if that adjacent levee reach is not categorized as Sound or Freeboard Deficient.

- Inspection reports. The standard for documentation of inspection is provided in 44 CFR 65.10(c)(1)(iii) and 44 CFR 65.10(c)(2)(iv).
- Elevation information for the levee.

- Certified as-built drawings.

All items must be certified and sealed by a registered P.E.

FEMA will review the submittal in accordance with Chapter 4 of this document.

6.15.2 Technical Procedures

No levee reach-specific modeling is required for a Sound Reach, but the Project Team will map the system-wide Zone D landward of the levee for these reaches. The SFHAs from the system-wide interior drainage analysis and/or adjacent levee reaches may still be present on the landside of Sound Reaches. (See Figure 22.) This will depend on the presence of interior ponding areas and other terrain features on the landward side of the levee. The SFHAs that form these areas will supersede the system-wide Zone D areas, as applicable.

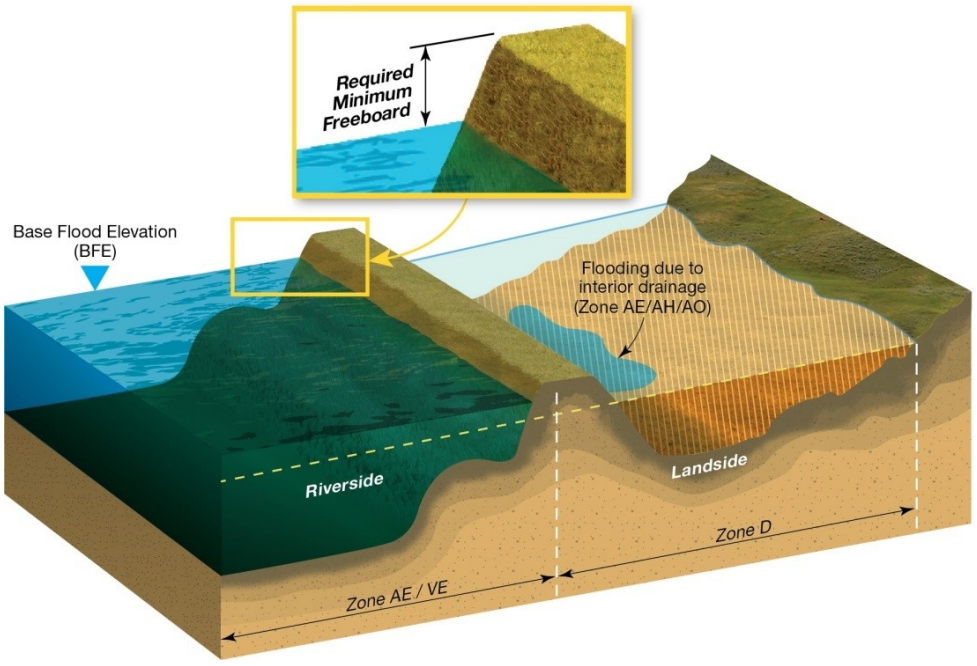

Figure 22: Sound Reach Cross-Section View

6.16 Flood Hazards Evaluated by Flooding Source (Figure 11, Element 630)

The assigned Project Team member will analyze and map the BFEs on the riverside of the levee assuming that all levee reaches remain intact. If a levee is overtopped and flow would be lost to the landside of the levee, the assigned team member may consider those losses and may reduce flow in the main flooding source in accordance with FEMA Guidance Document No. 80, Guidance for Flood Risk Analysis and Mapping - Hydraulics: One Dimensional Analysis, which is accessible from the FEMA Guidelines and Standards for Flood Risk Analysis and Mapping webpage.

6.17 Hydrograph Development

6.17.1 Riverine Hydrograph Development

Traditionally, projects conducted for flood insurance purposes have only calculated peak-flow or peak-surge elevation. Both the Structural-Based Inundation and Overtopping Procedures will often require a base flood hydrograph to complete the modeling, making the development of a flood hydrograph necessary. Computing and selecting a representative hydrograph shape with an appropriate volume is an important step. For many systems, the hydrograph shape and volume will be a key parameter influencing the resultant SFHA delineations.

FEMA determines that a cost-effective method is needed to estimate flood hydrographs for projects where only peak discharges/surge elevations are available, where a rainfall-runoff model or storm surge model is not available, or where funding is not sufficient to develop a rainfall-runoff or storm surge model. Procedures discussed below will use the base flood hydrograph for the levee analysis, but other flood return frequencies also could be used if appropriate.

The approach presented in this subsection is based on both the availability of data and the type of flooding. For flooding sources with gaging stations near the study location, two methods for developing desired-percent-chance flood hydrographs may be followed:

1. Scale a major (10-percent-annual-chance peak discharge or larger) observed flood hydrograph by multiplying the ordinates by a factor to create the desired-percent-chance flood hydrograph.
2. Develop a balanced synthetic flood hydrograph using peak discharges and N-day volumes.

The above methods for developing flood hydrographs are not the only acceptable approaches. The application of any method, including those above, should be evaluated for reasonableness.

The balanced synthetic flood hydrograph will be used when no major (10-percent-annual-chance peak discharge or larger) observed flood hydrograph is available for scaling to obtain the desired-percent-chance hydrograph, or the volume under the observed flood hydrograph is not considered representative of the desired-percent-chance hydrograph.

To scale a smaller hydrograph to a larger hydrograph, the assigned Project Team member will plot several observed flood hydrographs to determine a representative hydrograph shape that can be scaled to become a desired-percent-chance flood hydrograph. The observed hydrograph with the largest peak discharge and volume is the most logical choice. Unit discharge data are available from the USGS Instantaneous Data Archive for many gaging stations from the late

1980s through September 2007. Since October 1, 2007, the unit discharge data are available on the National Water Information System (NWIS).

The discharge ordinates of the representative observed hydrographs can be scaled by multiplying them by a ratio of the desired-percent-chance peak discharge to the observed peak discharge (or the reverse ratio if scaling down the observed hydrograph). If the gaging station drainage area is within 50 percent of the drainage area of the study location, the assigned Project Team member can transfer the desired-percent-chance hydrograph upstream or downstream using the ratio of drainage areas and regional flood frequency relations. Scaling the peak discharge also scales the flood volume with the time base of the hydrograph held constant (basin lag time assumed constant for a given watershed).

The above procedure is valid for steady flow. For unsteady flow, the Project Team member must take volume into consideration for hydrograph development.

The balanced synthetic hydrograph can be constructed using desired-percent-chance flood volumes for different durations (e.g., 1-day, 3-day, 7-day). The N-day flood volumes can be obtained from daily discharge data in the NWIS. Some of the available computer programs for estimating the desired-percent-chance N-day flood volumes include the USACE Hydrologic Engineering Center Statistical Software Package (HEC-SSP) and USGS Surface-Water Statistics (SWSTAT) computer program. The balanced synthetic hydrograph is shaped using an observed major flood hydrograph. More information on this method is provided in the USBR Flood Hydrology Manual and in USACE Engineer Manual 1110-2-1415, Hydrologic Frequency Analysis (or subsequent updates on this topic).

If the effective FIS Report was based on a rainfall-runoff model, the assigned Project Team member can use that model to obtain the appropriate flood hydrograph for ungagged watersheds. If a rainfall-runoff model was not developed for the effective FIS Report, a rainfall-runoff model may have been developed for other purposes, such as a master drainage plan. If available, the team member can scale the flood hydrographs from that model to be consistent with the peak discharges developed for the effective FIS Report.

If a continuous simulation rainfall-runoff model is available, then several simulated flood hydrographs are available. The assigned Project Team member can scale the simulated flood hydrograph with largest volume and peak discharge to get the desired-percent-chance flood hydrograph.

If no rainfall-runoff model is available, it may be feasible for the assigned Project Team member to develop a simplified rainfall-runoff model for a single watershed area with no subdivision and no channel/reservoir routing or model calibration. The team member can scale the flood hydrographs from this model to be consistent with peak discharges determined from other methods.

Examples of dimensionless unit hydrographs are provided in Figure 23, where the vertical ordinate is a ratio of discharge (Q) to the peak discharge (Qp) and the horizontal ordinate is a ratio of time (t) to basin lag time (T_L) to time to peak (T_P).

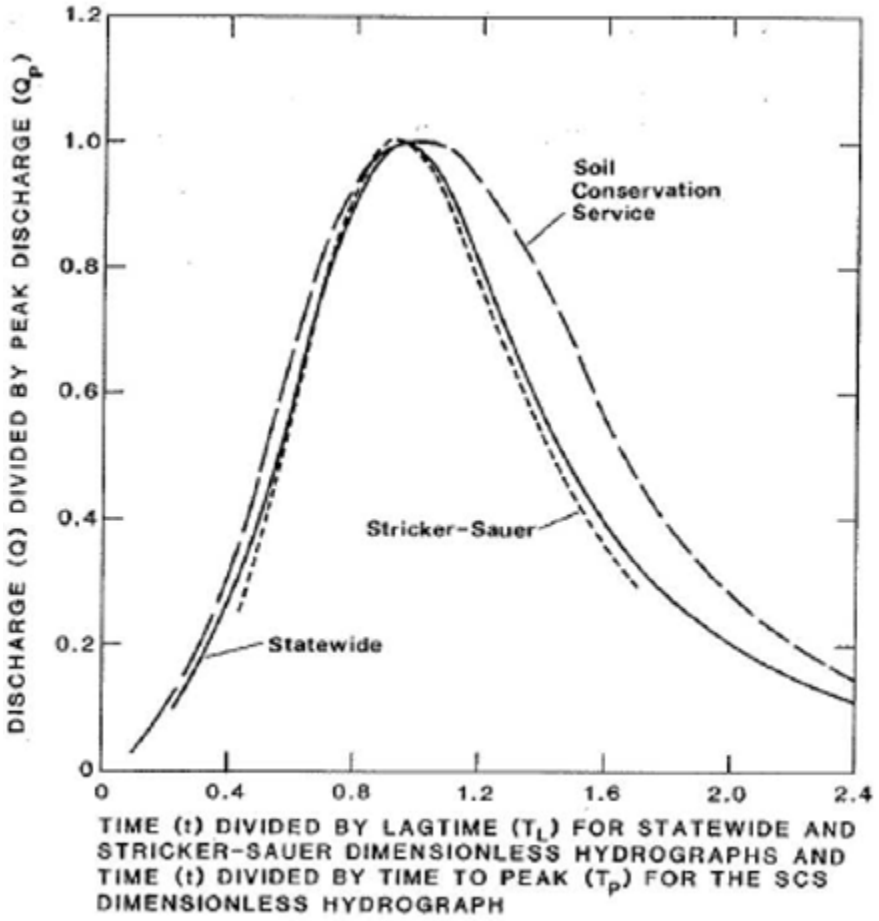

Figure 23: Sample Dimensionless Unit Hydrograph

The "Statewide" hydrograph in Figure 23 was developed by E, J. Inman in USGS Water-Supply Paper 2317, Simulation of Flood Hydrographs for Georgia Streams, using data for 80 gaging stations in Georgia. This dimensionless hydrograph is implemented in the USGS National Streamflow Statistics (NSS) Computer Program. The "Stricker-Sauer" hydrograph (USGS Open-File Report 82-365, Techniques for Estimating Flood Hydrographs for Ungaged Urban Watersheds), was theoretically developed from Clark unit hydrograph procedures. The "SCS" dimensionless hydrograph is described in Chapter 16, Part 630, Hydrology, of the Natural Resources Conservation Service (NRCS) National Engineering Handbook. The USGS dimensionless hydrographs shown in Figure 23 (Stricker-Sauer) can be converted to desired-percent-chance flood hydrographs by multiplying the discharge ratio by the desired-percent-chance peak discharge and the time ratio by basin lag time. The resultant flood hydrograph is assumed to be a typical flood hydrograph for a desired-percent-chance peak discharge. There is no implication that the volume under the hydrograph has a desired-percent chance of being exceeded. The desired-percent-chance peak discharge and the basin lag time are watershed-specific characteristics that determine the shape of the hydrograph.

Other flood hydrograph estimation methods developed by State, regional, and local agencies can be used in a similar manner. In the more arid regions of the Western United States, methods

developed by State, regional, and local agencies may be particularly relevant because the USGS national dimensionless hydrograph was developed for streams in Georgia and other USGS statewide analyses are generally restricted to the Eastern United States.

In addition to the Georgia dimensionless hydrograph ("statewide") available in the USGS NSS program, the USGS has developed dimensionless hydrographs for several other states:

- Water-Resources Investigations Report 89-4076, Techniques for Simulating Flood Hydrographs and Estimating Flood Volumes for Ungaged Basins in East and West Tennessee.
- Water-Resources Investigations Report 89-4087, Determination of Flood Hydrographs for Streams in South Carolina: Volume 1. Simulation of Flood Hydrographs for Rural Watersheds in South Carolina.
- Water-Resources Investigations Report 97-4279, Techniques for Simulating Peak-Flow Hydrographs in Maryland.

The dimensionless hydrographs developed for other states agree reasonably well with the Georgia dimensionless hydrographs, but the state-specific hydrographs are to be used if available. For ungaged streams that are not regulated by flood-control structures, the dimensionless hydrograph method may be used to estimate the desired-percent-chance hydrograph.

The desired-percent-chance peak discharge for rural and urban ungaged watersheds may be estimated from USGS regression reports or from other regression equations developed for the study area. The basin lag time may be estimated by regression equations given in USGS reports on dimensionless hydrographs, many of which are summarized in Appendix B of USGS Techniques and Methods 4-A6, The National Streamflow Statistics Program: A Computer Program for Estimating Streamflow Statistics for Ungaged Sites, and other regression equations developed for basin lag time. The basin lag time as used in the USGS dimensionless hydrograph approach is the time from the center of mass of rainfall excess to the center of mass of runoff.

Using rainfall-runoff data for 81 watersheds in Maryland, in Estimation of Time of Concentration for Maryland Streams, Thomas and others demonstrated that the basin lag time used to define the USGS dimensionless hydrograph was, on average, only 5 percent less than the watershed time of concentration. Therefore, basin lag time as defined above may be approximated by the time of concentration as estimated by the NRCS travel time method documented in Technical Release 55, Urban Hydrology for Small Watersheds.

The balanced synthetic hydrograph method described above for gaged streams may also be applied to ungaged streams by implementing the method below.

- Estimate N-day volumes (e.g., 1-day, 3-day, 7-day) at gaging stations in the vicinity of the ungaged streams.
- Develop regression equations for estimating the desired-percent-chance N-day volumes for ungaged streams.

- Construct a balanced synthetic hydrograph with the desired-percent-chance N-day volumes.

This method is more time consuming, but it may be used if the dimensionless hydrograph method does not provide reasonable results or in areas where the dimensionless hydrograph method may not be applicable.

6.17.2 Coastal Hydrograph Development

For coastal analyses, one way to create a synthetic storm surge hydrograph is using procedures in the Federal Highway Administration (FHWA) Hydrologic Engineering Circular No. 25, Tidal Hydrology, Hydraulics, and Scour at Bridges. If data from a detailed coastal model are not available. The required variables for the method are:

- Peak surge elevation (S_p)
- Forward speed of the storm (f)
- Radius of maximum winds (R)

S_p is given directly from the published BFE noted in the FIS Report, while a range of values for both R and f are possible for a given location.

Coastal Flood Risk Projects based on modern methods involving Joint Probability Method (JPM) analysis contain enough information about the range of storm parameters that a representative R and f to associate with the value of S_p can be calculated directly. For flood hazard mapping projects where the Project Team did not employ a JPM approach for determining the BFE, these values may need to be estimated by examining historical storms in the region.

Pilot tests suggest that the ultimate extent of flooding landward of a breached or overtopped coastal levee is not highly sensitive to the shape of the synthetic hydrograph, so the exact choice for f and D may not be a critical factor. The peak surge and width of failure in a breaching condition is of primary importance within this analysis.

6.18 Regulatory Floodways

For some communities, regulatory floodways may have already been delineated for levee-impacted areas along a flooding source. FEMA has developed an approach for modeling and delineating the regulatory floodway in levee-impacted areas.

The following guiding principles form a basis to support this effort and are discussed in more detail in the subsections that follow:

1. Baseline Model
   The baseline model is either the effective model (for the base flood event) if an effective floodway exists or the baseline model does not consider any existing encroachments since the area was first shown on an NFIP map.

2. Surcharge Limits (Values)

   NFIP regulations and Standard SID 69 states:

Floodway surcharge values must be less than or equal to 1.0 ft. If the state (or other jurisdiction) has established more stringent regulations, these regulations take precedence over the NFIP regulatory standard. Further reduction of maximum allowable surcharge limits can be used if required or requested and approved by the communities impacted". Standard SID 70 states "If a stream forms the boundary between two or more states and/or tribes, either the 1.0-foot maximum allowable rise criterion or existing floodway agreements between the parties shall be used.

3. Effective Floodway

   a. Existing Conditions - Presence of an effective floodway provides a starting point for:

      1. Baseline model; and

      2. Floodway encroachment.

      If no effective floodway exists, then the baseline model using equitable consideration of both overbanks becomes the initial floodway analysis.

   b. Proposed or Changed Conditions - If the proposed or changed project results in BFE increases in excess of those permitted under 44 CFR 60.3 (c)(10) or (d)(3), the community must apply for CLOMR per 44 CFR 65.12. CLOMRs are encouraged for all levee projects.

4. Equal Conveyance

   Standard SID 73 states: "A methodology based on equitable consideration of both overbanks must be used to establish the minimal regulatory floodway. Variations to this approach must be made in coordination with FEMA and impacted communities.

5. Removal or No Floodway

   In some situations, floodways may not make sense if there is already a built-out condition, or other flow conditions not supporting a floodway analysis exists. In these situations, coordination with FEMA and affected communities is needed to come to an agreement on the proper approach.

6. Hydraulically Insignificant Levees (refer to Subsection 6.19.3)

   For levees which are considered hydraulically insignificant, that is, the levee does not significantly affect the natural flow through the valley or is significantly overtopped during the base flood event, the floodway is modeled using the Natural Valley Procedure with initial floodway analyses using the current floodway procedures. For mapping purposes, a structure is considered hydraulically insignificant if, during a base flood event, the peak WSELs landward of the structure may be the same regardless of whether the structure was in place.

7. Hydraulically Significant Levees (refer to Subsection 6.19.4)
   For levees which are considered hydraulically significant, which can include accredited levees and/or non-accredited levees, the floodway is computed in one of two ways:

   a. Levee on one bank

b. Levee on both banks

8. Mapping Floodway Boundaries on the Levee
   Standard SID 452 states, “Floodway boundaries shall be placed on the riverside of a levee unless the community specifically requests otherwise, or where hydraulic calculations demonstrate a floodway is warranted elsewhere”. Where the floodway boundary lands on the levee, the boundary is placed at the computed location, unless the State or community request otherwise. Some States, who have jurisdiction over the floodways, regularly show the floodway boundaries on the landside toe. The floodway should not extend past the landside toe for an accredited levee without concurrence from the FEMA Regional Office and FEMA Headquarters.

6.18.1 Coordination with Communities

The regulatory floodway is a community floodplain management tool. While a default approach is presented below, FEMA decisions about the final approach to determining the regulatory floodway will be made in coordination with officials of the affected communities, the levee owner(s), and impacted property owners. In addition, when the jurisdictions along either side of a flooding source are different, coordination between the Project Team, the State NFIP Coordinator(s), and local jurisdictions affected will need to take place before the modeling approach is finalized.

Development and designation of floodways in urban situations where significant development has already occurred may not be beneficial to the community as minor public and homeowner projects will need to demonstrate “no-rise” in the BFE. In such situations, designation of a floodway hinders floodplain management rather than aids it. A more equitable solution could be to actively manage development using the model to prevent development from creating more than the cumulative allowable rise, per the code of federal regulations, if the community has this capability. Such situations require additional coordination among FEMA, the State, and the communities.

6.18.2 Floodway Analysis and Mapping Methods

The floodway should be modeled as described in FEMA Guidance Document No. 79, Guidance for Flood Risk Analysis and Mapping: Floodway Analysis and Mapping. Per this guidance, the baseline model for the allowable surcharge is the model used to determine the BFEs the first time a floodway was adopted for the reach. Unless it is demonstrated that the model should be revised for reasons other than encroachments into the floodplain, all subsequent revisions to the floodway are limited to the maximum allowable surcharge above the elevations determined in the base model. That way, as hydraulic models are updated to reflect encroachments into the floodway fringe, the cumulative effect of those and future encroachments is limited to the maximum allowable surcharge.

In case of leveed reaches, it is acceptable to compare the floodway WSELs to the “with-levee" BFEs to determine surcharges if acceptable surcharge limit cannot be achieved using the baseline WSEL. In these situations, the methodology outlined in the following subsections limit the floodway encroachments at the levee. Coordination with FEMA and community officials is required in case the encroachment location on the riverside of the levee is warranted. Generally, the floodway analysis in leveed reaches consist of up to three parts:

1. An initial floodway analysis to determine the natural valley based on equitable reduction on both overbanks to set the regulatory floodway location.

2. An intermediate floodway analysis to verify that the allowable surcharges are not exceeded with the levee in place.

3. A final floodway analysis that has surcharges within the allowable limits.

The conditions used for the baseline model and the floodway analyses steps listed above (and described below) could vary on case-by-case basis. Coordination with FEMA and the affected communities will be required in these cases.

6.18.3 Hydraulically Insignificant Levees

If a levee is determined to be hydraulically insignificant and the Natural Valley Procedure is used, the regulatory floodway may still extend landward of the levee. The assigned Project Team member will develop the floodway analysis following established standards and procedures. In addition, if the levee is overtopped during the base flood event and a defined flow path must be preserved, the assigned team member may find that a floodway analysis of the flow path may be required.

6.18.4 Hydraulically Significant Levees

If a levee(s) is determined to be hydraulically significant, the procedures outlined below are applied for floodway modeling. It is likely that a combination of the scenarios discussed below will exist at various cross sections along the levee system. The methods described in Subsections 6.19.5 through 6.19.9 can be applied to specific cross sections. However, the Project Team should evaluate consideration of the model as a whole when adjusting encroachment stations due to the impact to surcharge values and community input.

6.18.5 Hydraulically Significant Levees – On One Bank

For streams with no effective floodway, an initial floodway analysis will be developed using the natural valley analysis with current standards and procedures. For streams with an effective floodway, an initial floodway analysis is performed using the natural valley analysis with the effective floodway encroachment stations to verify that the allowable surcharge limits can still be met. If the initial floodway analysis resulted in floodway encroachment stations on the riverside of the levee and meeting the allowable surcharge limits, the floodway can be delineated at the computed locations. If the floodway limit is located on the riverside of the levee and the impacted State and/or community with jurisdiction over the floodway requests, FEMA will map the floodway limit on the landside toe of the levee for an accredited levee system. In case of a non-accredited levee system, States or communities may decide to delineate the floodway at the computed location within the levee-impacted area. In these cases, the intermediate steps discussed below are not necessary.

If the initial floodway analysis resulted in a floodway encroachment landward of the levee (see Figure 24), an intermediate floodway analysis can be developed. This is done by maintaining the location of the encroachment stations on the non-leveed side and shifting the leveed-side encroachment stations to the levee line. (See Figure 25.) The resulting regulatory floodway elevations are compared to the baseline without floodway elevations to determine if the surcharges are within the allowable limit. If the surcharges are within the allowable limit, the floodway can be delineated at the location computed in this model.

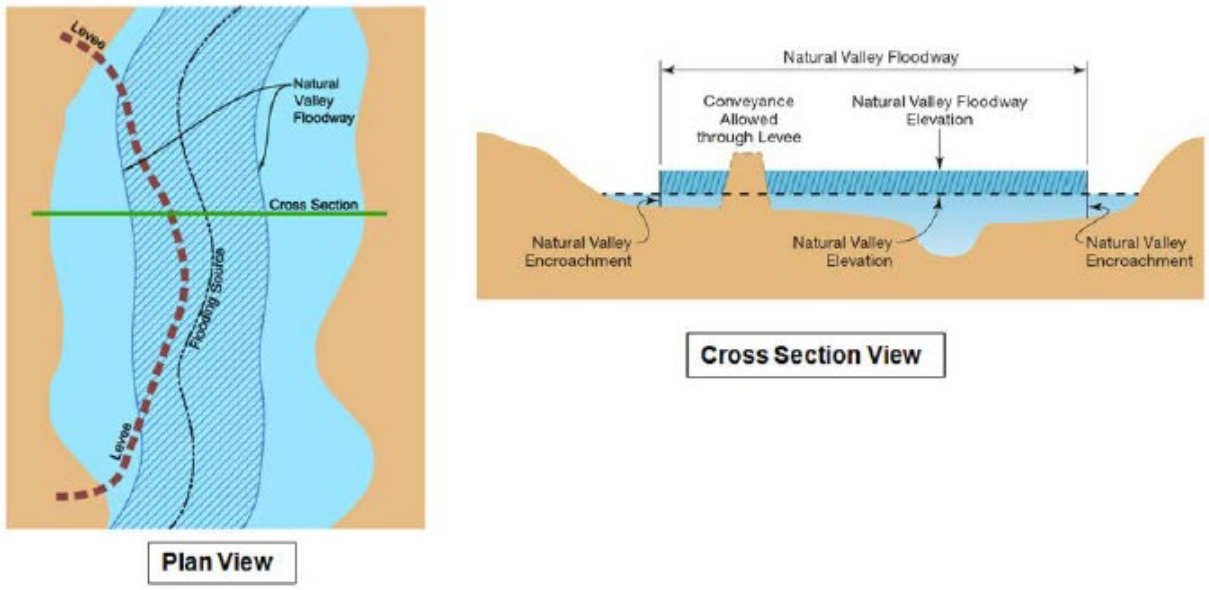

Figure 24: Floodway Analysis Process Initial Analysis

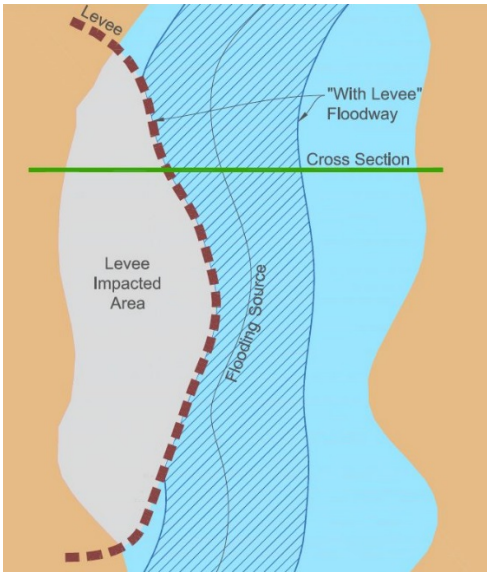

Figure 25: Floodway Analysis Process Initial Analysis

If surcharge in the intermediate floodway model exceeds the maximum allowable limit, the regulatory floodway on the non-levee side is widened to bring the surcharge within the allowable limit, as shown in Figure 26. This condition would require coordination with the State or community officials and affected property owners. If the surcharges cannot be kept within allowable limit by widening the non-levee side, the surcharge can be reevaluated by comparing the results of the intermediate floodway analysis to the with-levee BFE. Situations may arise where it is not possible to bring the floodway surcharge within allowable limit by widening the floodway or evaluating the surcharges against the with-levee BFEs. In these situations, coordination among community officials, affected property owners, and FEMA is required to determine the most appropriate approach.

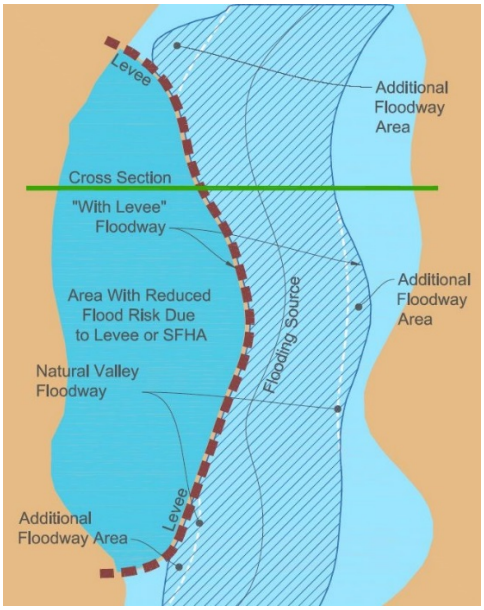

Figure 26: Final Regulatory Floodway

6.18.6 Hydraulically Significant Levees on Both Banks

When hydraulically significant levees exist on both banks, three scenarios could potentially result from the initial natural valley floodway analysis methodology outlined in Subsection 6.19.2.

- Both encroachment stations computed on the levees or on the riverside of the levees.
- One encroachment station is computed on the landside of the levee and the other is on or riverside of the levee.
- Both encroachment stations are computed on the landside of the levees.

6.18.7 Both Encroachment Stations Computed on Levee or on Riverside of Levee

If the initial floodway analysis resulted in a floodway encroachment on the riverside of the levee on both sides (Figure 27), the floodway can be delineated at the computed location. However, if requested by the community, the floodway may be mapped at the landside toe of the levees.

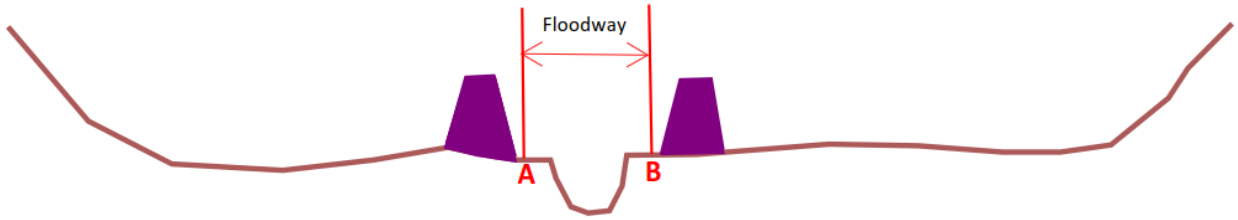

Figure 27: Both Encroachments (A and B) on Riverside of Levees

6.18.8 One Encroachment Station Is on Landside of the Levee and the Other Is on the Levee or on the Riverside of the Levee

If the initial floodway analysis resulted in a floodway encroachment on the riverside of the levee on one side and on the landside of the levee on the other side, as shown by points A and B, respectively, in Figure 28 below, then an intermediate floodway analysis will be developed.

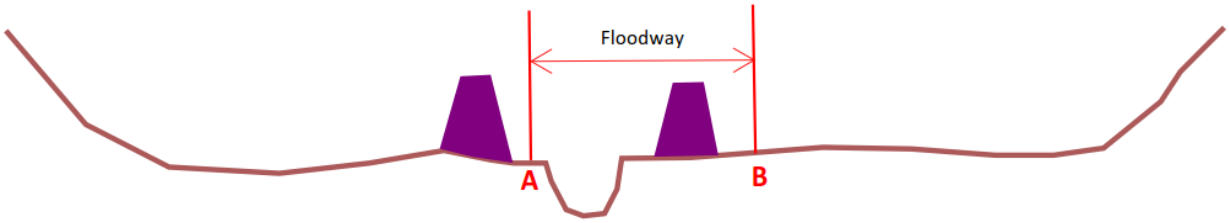

Figure 28: One Encroachment on Riverside of Levee (A) and the Other on Landside of Levee (B)

This is done by maintaining the location of the encroachment station A and shifting encroachment station B to the levee location as shown in Figure 29. The resulting regulatory floodway elevations are compared to the baseline model elevations to determine if the surcharges are within the allowable limit. If the surcharges are within the allowable limits, the floodway can be delineated at the location computed in this model. If requested by the community, the floodway on one or both sides may be mapped at the landside toe of the levee.

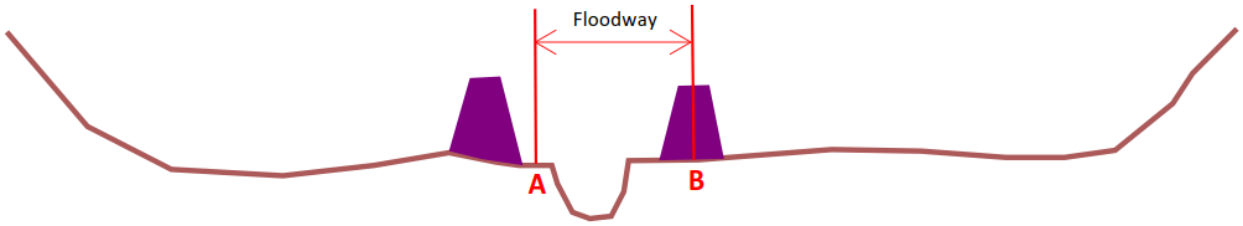

Figure 29: The Landside Encroachment (B) Moved to the Levee

If surcharge in the intermediate floodway model exceeded the maximum allowable, the regulatory floodway on side A is widened to bring the surcharge within the allowable limits, as shown in Figure 30. If the surcharge limit cannot be met by moving the encroachments to the levees, the surcharge can be reevaluated by comparing the results of the intermediate floodway analysis to

the with-levee BFE. Situations may arise where it is not possible to bring the floodway surcharge within the allowable limit by widening the floodway and using the with-levee BFE for surcharge calculation. Coordination between community officials and FEMA is required to determine the most appropriate approach.

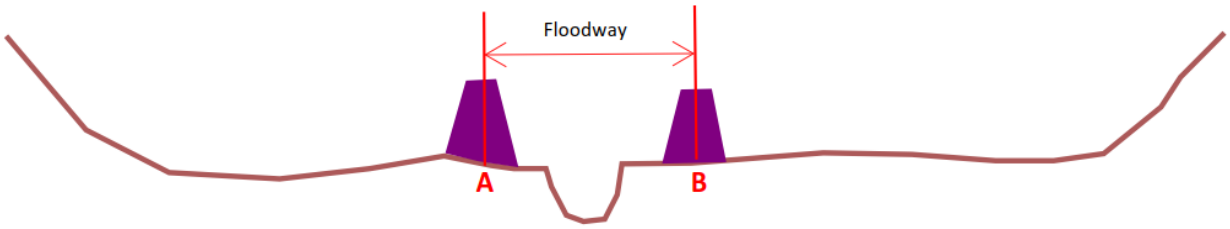

Figure 30: Both Encroachments at Levees

6.18.9 Both Encroachment Stations Fall on Landside of the Levees

If the initial floodway analysis resulted in a both floodway encroachments on the landside of the levees on both banks, as shown in Figure 31 below, then an intermediate floodway analysis will be developed. This is done by moving both encroachments to the levee (as shown in Figure 30) and comparing the floodway elevation to the baseline model elevations to determine if the surcharges are within the allowable limits. If they are within the allowable limits, then the floodway is mapped at the levees.

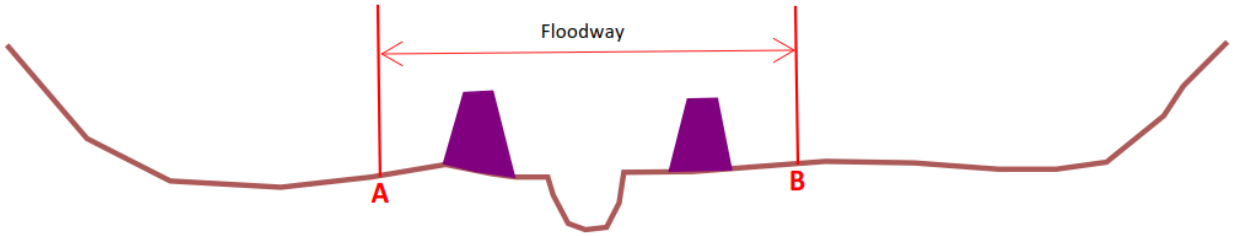

Figure 31: Both Encroachments Landward of the Levees

If surcharge in the intermediate floodway model exceeded the maximum allowable, the surcharge can be reevaluated by comparing the results of the intermediate floodway analysis to the with-levee BFE. If the surcharges are within allowable limit, the floodway can be mapped at the levees. If the surcharges exceed the allowable limit, coordination between community officials and FEMA is required to determine the most appropriate approach.

6.18.10 The Methodology for Development of the Regulatory Floodway

This subsection outlines the step-by-step process for determining the final floodway encroachment stations for hydraulically significant levees on both banks. Steps 5 and 6 apply only to non-accredited levees.

As mentioned in previous sections, the regulatory floodway is a community floodplain management tool, and the final approach to determining the regulatory floodway will be made in coordination between FEMA and the affected communities. The method below is a general guideline expected to be applicable for floodway identification in most levee situations. These

steps should be applied in consideration of the model as a whole when adjusting encroachment stations.

1. Compute the WSEL with both levees holding to produce the with- levee BFE.
2. Compute the WSEL with the left levee holding (BFE riverside of right levee).
3. Compute the WSEL with the right levee holding (BFE riverside of left levee).
4. Perform the Natural Valley Procedure floodway analysis to determine encroachment stations A and B. (See Figure 32.)

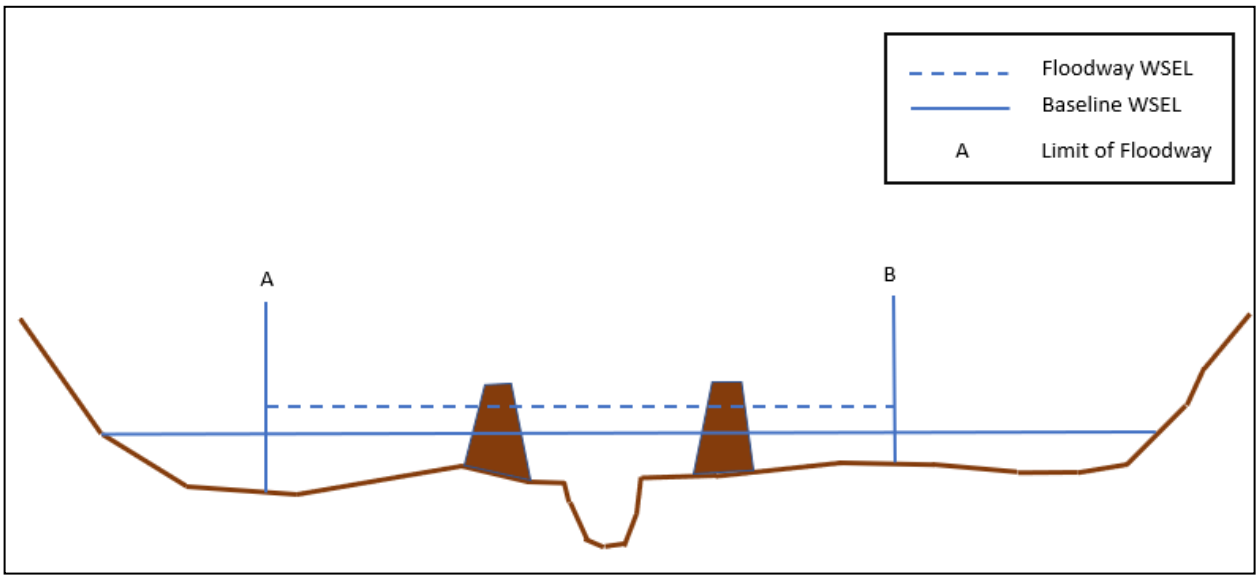

Figure 32: Use of Natural Valley Procedure to Determine Initial Encroachment Stations A and B

5. Run floodway analysis with the left levee holding to determine encroachment station C. Left encroachment station is set at the left levee. (See Figure 33.)

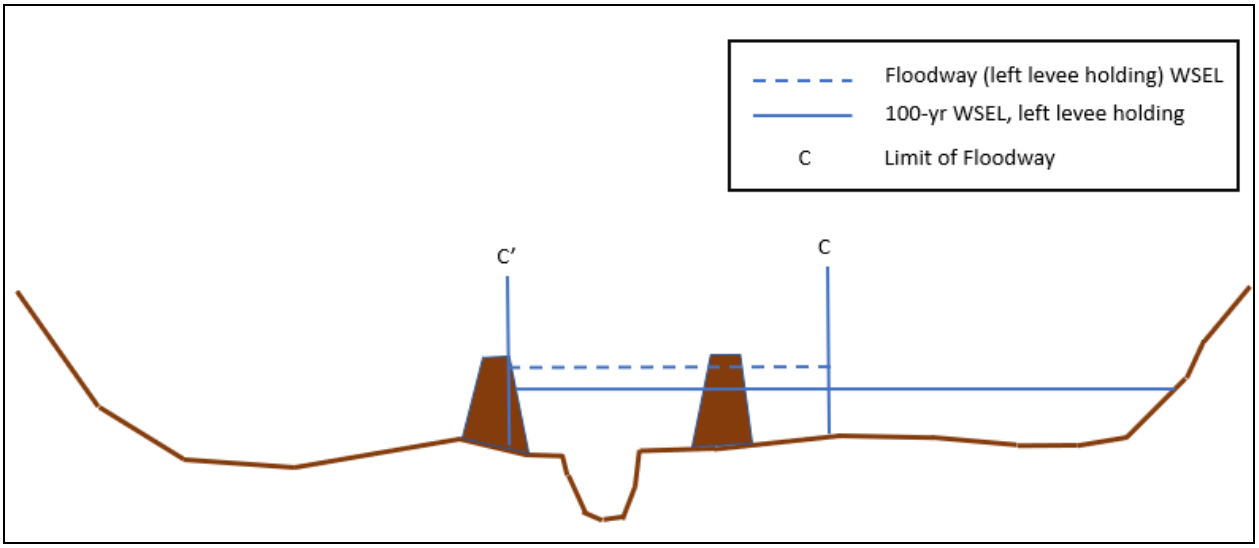

Figure 33: Using Left levee holding to find encroachment station C

6. Run floodway analysis with the right levee holding to determine encroachment station D. Right encroachment station is at the right levee. (See Figure 34.)

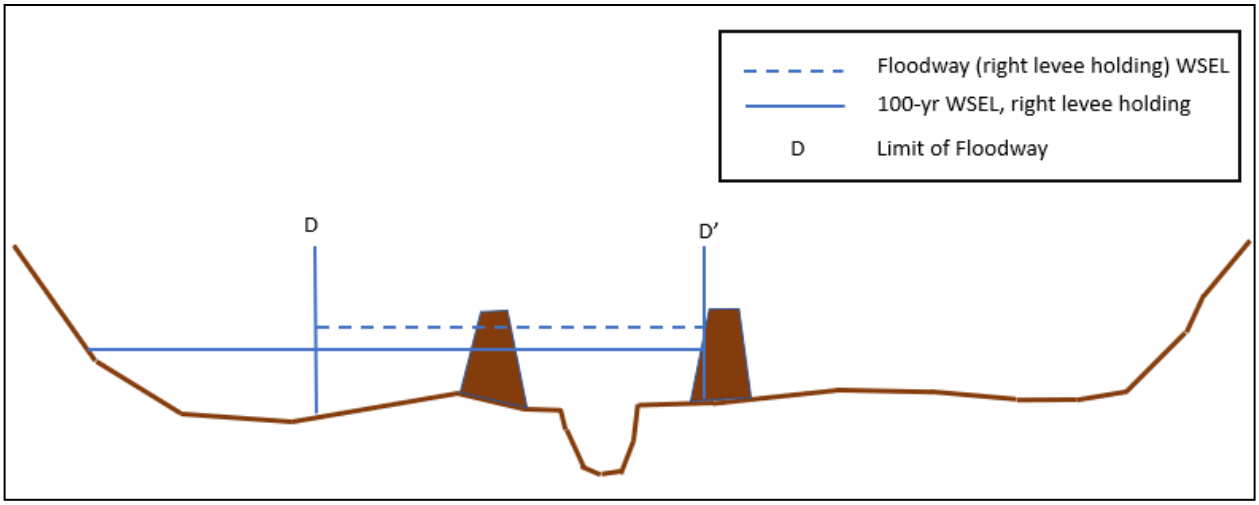

Figure 34: Right Levee Holding to Find Encroachment Station D

7. If both levee systems are accredited, start with A and B as initial locations as shown in Figure 32. If both levees are non-accredited, start with C and D as initial locations from encroachments computed in previous steps. (See Figure 35.) if the left levee is non-accredited and right levee is accredited, start with B and D as initial locations from encroachments computed in previous steps. (See Figure 36.) If the right levee is non-accredited and left levee system is accredited, start with A and C as initial locations from encroachments computed in previous steps. (See Figure 37.) Then follow the steps outlined below.

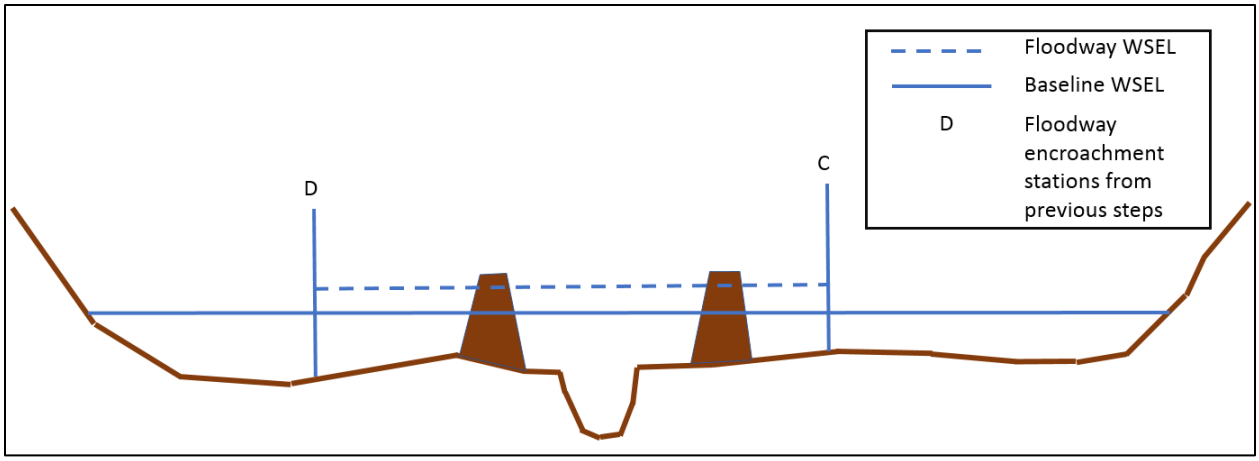

Figure 35: Both levees Are Non-accredited

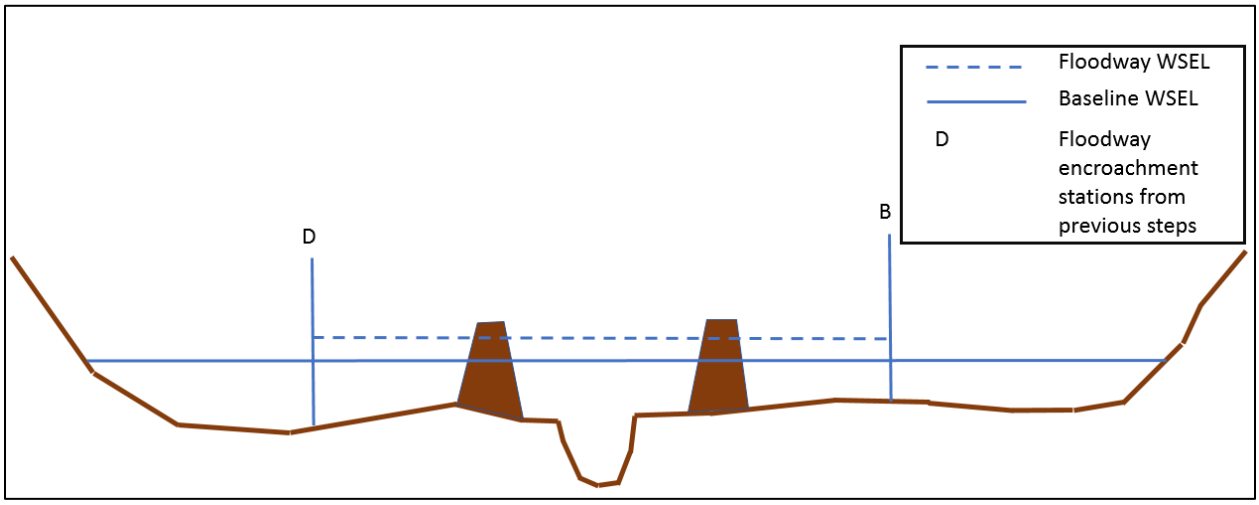

Figure 36: Left Levee Is Non-accredited, Right Levee Is Accredited

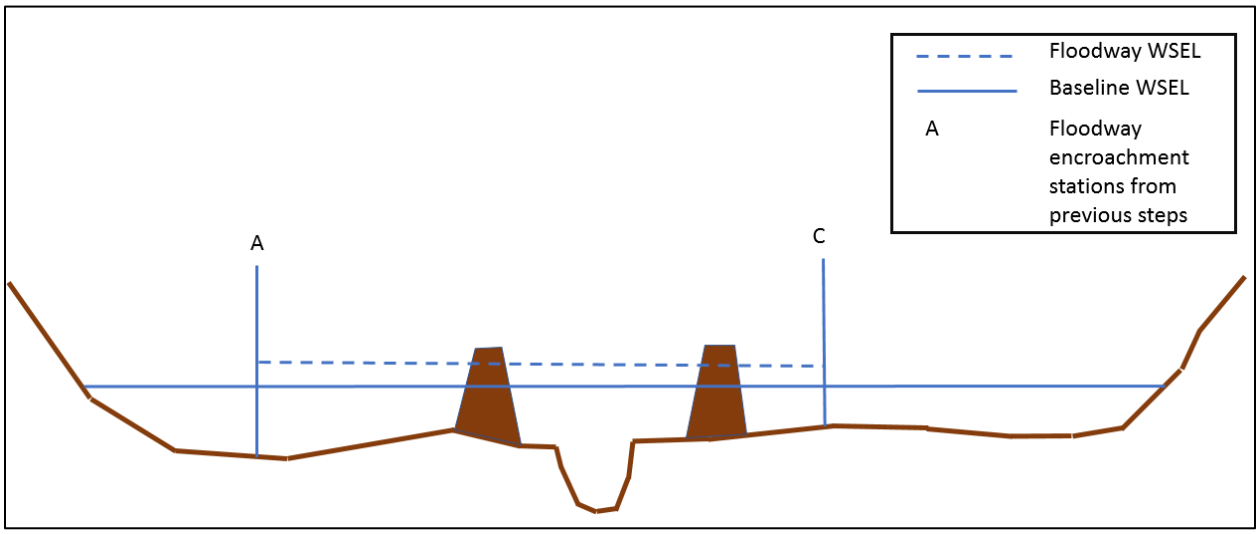

Figure 37: Right Levee Is Non-accredited, Left levee Is Accredited

a. Start with initial encroachment stations from Step 7. Compute the surcharge for the floodway using the baseline WSEL. If the surcharges are within the maximum allowable limit, and both the left and the right encroachments are on the riverside of the levee, the floodway analysis is complete. The floodway is mapped on the riverside of the levee at the final computed location.

b. If the surcharges are higher than the maximum allowable limit and the encroachments are on the riverside of the levee, move the encroachments to the levees (C' and D'). If the surcharge is within the allowable limits, the floodway analysis is complete. If the surcharge is still higher than the allowable limits, proceed to Step d.

c. If both or either of the encroachments are on the landside of the levee, then move the landside encroachment(s) to the levee(s) (C' and/or D') and test if surcharge is within allowable limit using the baseline water-surface elevation. If it is within the allowable limit, the floodway analysis is complete. If the surcharge is higher than allowable, move the riverside encroachment to the levee (C' or D') where applicable, and test if the surcharge is within allowable limits. If it is, the floodway analysis is complete. If the surcharge is still higher than the allowable limits, proceed to Step d.

d. If surcharges with encroachments set at the levees are higher than the allowable limit using the baseline WSEL, evaluate whether the allowable surcharge can be met by widening encroachments at the non-leveed cross sections. If the surcharge is still higher than the allowable limits, test the surcharge using the with-levee WSEL. If the surcharge is within allowable limits using the with-levee baseline, then the analysis is complete. If the surcharge is still higher than the allowable limits, proceed to Step e (for non-accredited levees) or Step f (for accredited levee systems).

e. In the case of non-accredited levee systems, if the surcharge with encroachments set at the levees is higher than the limit using the with-levee baseline WSEL, encroachments C and D can be moved to the landside of the levees until the allowable surcharge is achieved. If the allowable surcharge limits cannot be met by moving the encroachment outward or the affected communities do not want a floodway on the landside of the levee, coordination between the community and FEMA is required to identify the appropriate approach.

f. In the case of accredited levee systems, if the surcharge with encroachments set at the levees is higher than the allowable limit using the with-levee baseline WSEL, typically encroachments A and B can be not moved to the landside of the levees. Adjust encroachments at adjacent non-leveed cross sections to achieve an allowable surcharge. If the allowable surcharge limits cannot be met by adjustment of encroachments at non-leveed sections, coordination between the community and FEMA is required to identify the appropriate approach.

6.19 Hydraulic Modeling on Landside of the Levee

This subsection presents recommended guidance to be used for the mapping of the landside flood hazard area for levee reaches that are evaluated using the Overtopping or Structural-Based Inundation Procedures. For these procedures, often an unsteady flow will be required. While Appendix C of FEMA's Guidelines and Specifications for Flood Hazard Mapping Partners

(discusses both one- and two-dimensional unsteady-flow modeling, this subsection provides additional guidance specific to levees.

The flood hazard area created by levee overtopping or breach is assumed to be subject to the same annual-chance flooding as the exterior flooding source. For example, if a levee is breached by the base flood, the assigned Project Team member will delineate the area on the landside of the levee as an SFHA on the FIRM.

Hydrologic or hydraulic analyses are necessary to compute the flood elevations created by the inflow. Reservoir routing and pump operation will be the features generally applied to determine flood elevations for hydrologic analyses.

One-dimensional (1-D), two-dimensional (2-D) steady flow, and unsteady flow solution methods are the hydraulic analysis methodologies applicable to compute flood elevations. The applicability and data requirements for these methodologies are summarized below.

6.19.1 Hydrologic Flow Routing

Hydrologic flow routing is applicable when floodplain storage, not conveyance, is the dominant factor determining the flood elevation. This will generally be applicable if the inflow is for a limited duration and the interior floodplain has the capability to store the volume of flow entering the impacted area. A stage-inflow hydrograph of the exterior flooding source is essential to determine the duration and rate of the inflow, and to conduct a hydrologic flow routing. Depending on the mode of failure, the assigned Project Team member can compute inflow hydrographs by applying appropriate hydraulic computations. Most hydrologic flow routing models also have the capability to reflect flow evacuation features, such as pumping stations.

6.19.2 Hydraulic Modeling

A hydraulic approach is applicable when an alternate flow path is created on the landside of the levee for floodwater to flow downstream. Conveyance and floodplain storage along the flow path are the dominant factors controlling the flood elevations. For general floodplain analyses based on the formulation of basic equations of motion, four types of solutions procedures are available. They are categorized as 1-D steady flow, 1-D unsteady flow, 2-D steady flow, and 2-D unsteady flow solutions. Where groundwater is close to ground level, it may be appropriate for the assigned Project Team member to account for groundwater interaction.

The Project Team can select any hydraulic analysis software accepted by FEMA for flood hazard area development for hydraulic modeling. General data requirements and applicability of the different types of hydraulic flow modeling are provided in Subsections 6.20.3 through 6.20.6.

6.19.3 One-Dimensional Steady Flow Analysis

One-dimensional steady flow analyses are applicable where flow is limited to defined flow paths. Inflow would be peak flow rates generated from the subject levee failure conditions – overtopping, segment failure, dynamic breach, or final breach condition. Weir and split flows are two commonly used options.

Inflow discharges due to overtopping can be computed by applying lateral weir flow computations. For weir flow assumptions to be applicable, the flow crossing the crest profile of the levee or flood wall must not be submerged on the landside of the levee. The weir flow method is also applicable if the final breach geometry creates weir-flow conditions.

When overtopping flow accumulated on the floodplain creates a fully submerged condition on the landside of the levee, split flow becomes applicable. When a breached levee fails to the natural ground level, inflow may be computed as split-flow conditions in the vicinity of the breach location. The breach or overtopping flow may return to the same river downstream, join another flooding source, or flow into a large water body whose WSEL will not noticeably change despite receiving the inflow from levee failure. In addition, most steady flow analyses can also reflect constant pumping rates.

One-dimensional steady flow models are generally not applicable in coastal situations.

6.19.4 One-Dimensional Unsteady Flow Analysis

Unsteady flow analyses are most suitable if the flow is limited to defined flow paths and defined storage areas are present in the overbank. However, unsteady flow models using link-node concepts to represent flow have the capability to model a larger number of flow paths and offline floodplain storage. Unsteady flow analyses have the capability to simulate online floodplain storage and dynamic impacts of pumping activities.

Unsteady flow analyses can be applied to a variety of downstream boundary conditions. Flow may rejoin the same river downstream, at other flooding sources, travel to storage/ponding areas, or reach an ocean impacted by daily tide level variations.

Unsteady 1-D numerical models also may be applied to model the hydraulics for coastal levee overtopping and breach scenarios. In selecting an appropriate model, consideration is to be given to models that include modules for incorporating flow-control structures and supercritical flow.

Models developed with modules accounting for dam-break scenarios may also be applied to levee breach scenarios. Models that are applicable to coastal flooding sources and include wave overtopping also exist and can be used.

6.19.5 Two-Dimensional Flow Analysis

Two-dimensional flow routing is most applicable to natural floodplains with flat terrain or urban floodplains where flow directions are dictated by streets, storm drain alignments, and obstructions caused by buildings. When levee breach or overtopping occurs, inflow from the channel may be modeled as 1-D flow near the breach and develop into 2-D flow, either forming flow paths or remaining as sheet flow to spread over the floodplain. A typical 2-D model can model levee, flow paths, street flow, or shallow flow conditions.

Generally, 2-D models have the capability to provide unsteady flow solutions. A hydrograph and can be generated outside of the 2-D model and provided as input. Inflow hydrographs can be computed using methodologies described for 1-D unsteady flow analysis. Some 2-D software accepted for flood study development can also model levee overtopping, piping, and slope stability failure as well as flow routing on the adjoining floodplain.

Two-dimensional analyses provide a convenient method to simulate multiple modes of failure at different locations without significant additional effort. Two-dimensional analysis is also applicable to simulate flood ponding in areas between two levees or areas impacted by ring levees. When a breach occurs in one of the levees, areas between two levees will be inundated until the ponding elevation reaches the equivalent elevation of the flooding source side or overtops the other levee. In the latter situation, the ponding elevation is to be mapped as the elevation of levee being overtopped. Pumping and other flood-mitigating features may be reflected in most 2-D models through rating curves.

The storm surge modeling system most prevalently used in coastal flood hazard studies includes the ADCIRC 2-D circulation model, which is then coupled with a 2-D wave model (STWAVE or UnSWAN). A 2-D model will have varying levels of complexity. A simple 2-D model using terrain data may be easily produced. In comparison, a complex 2-D model that includes detailed hydraulic structures and streets may be time-consuming to prepare.

6.19.6 Combination of One-Dimensional and Two-Dimensional Models

Increasingly, 1-D unsteady flow and 2-D software developers have provided the capability to link 1-D and 2-D solutions as needed. Users have the capability to use the appropriate solutions for appropriate locations. Some such models also have options to model the levee breach process. The channel flow is typically modeled as 1-D, using cross sections. Landside flow from a levee breach or overtopping is routed using 2-D grids or finite element mesh.

The selected analysis methodology should be able to reflect flow conditions adequately and develop reliable flood elevations and flood hazard area boundaries for the area landward of a levee that does not meet the 44 CFR 65.10 criteria. Decision factors include the consequences of levee failure, nature of the terrain, complexity of the levee systems, mode of failure mechanisms, data availability, and availability of funds.

6.20 Flood Hazard Mapping

6.20.1 Mapping Process

In the event that a stakeholder disagrees with the final analysis and mapping procedures used to create the FIRM, the current FEMA appeals and Scientific Resolution Panel procedures may be used. These procedures are documented in FEMA Guidance Document No. 26, Guidance for Flood Risk Analysis and Mapping: Appeal and Comment Processing. The guidance document is accessible from the FEMA Guidelines and Standards for Flood Risk Analysis and Mapping webpage.

The final mapped flood hazard boundaries landward of non-accredited levee systems will be a worst-case combination of three main sources:

1. The composite SFHA resulting from the levee reaches evaluated by the Overtopping, Structural-Based Inundation, or Natural Valley Procedures for each levee reach. Sound and Freeboard Deficient levee reaches will not have an SFHA associated with the individual reach analysis.
2. The SFHA resulting from the interior drainage analysis.

3. The area developed using the Natural Valley Procedure, which will be used to depict the potential base flood hazard that exists landward of a non-accredited levee system in areas where an SFHA has not been identified. This Zone D will be shaded on the FIRM differently than a typical Zone D to clarify the difference in how the two zones are developed.

This concept is illustrated in Figure 38. If BFEs are to be shown on the FIRM, they will be based on the highest elevation of the composite mapping.

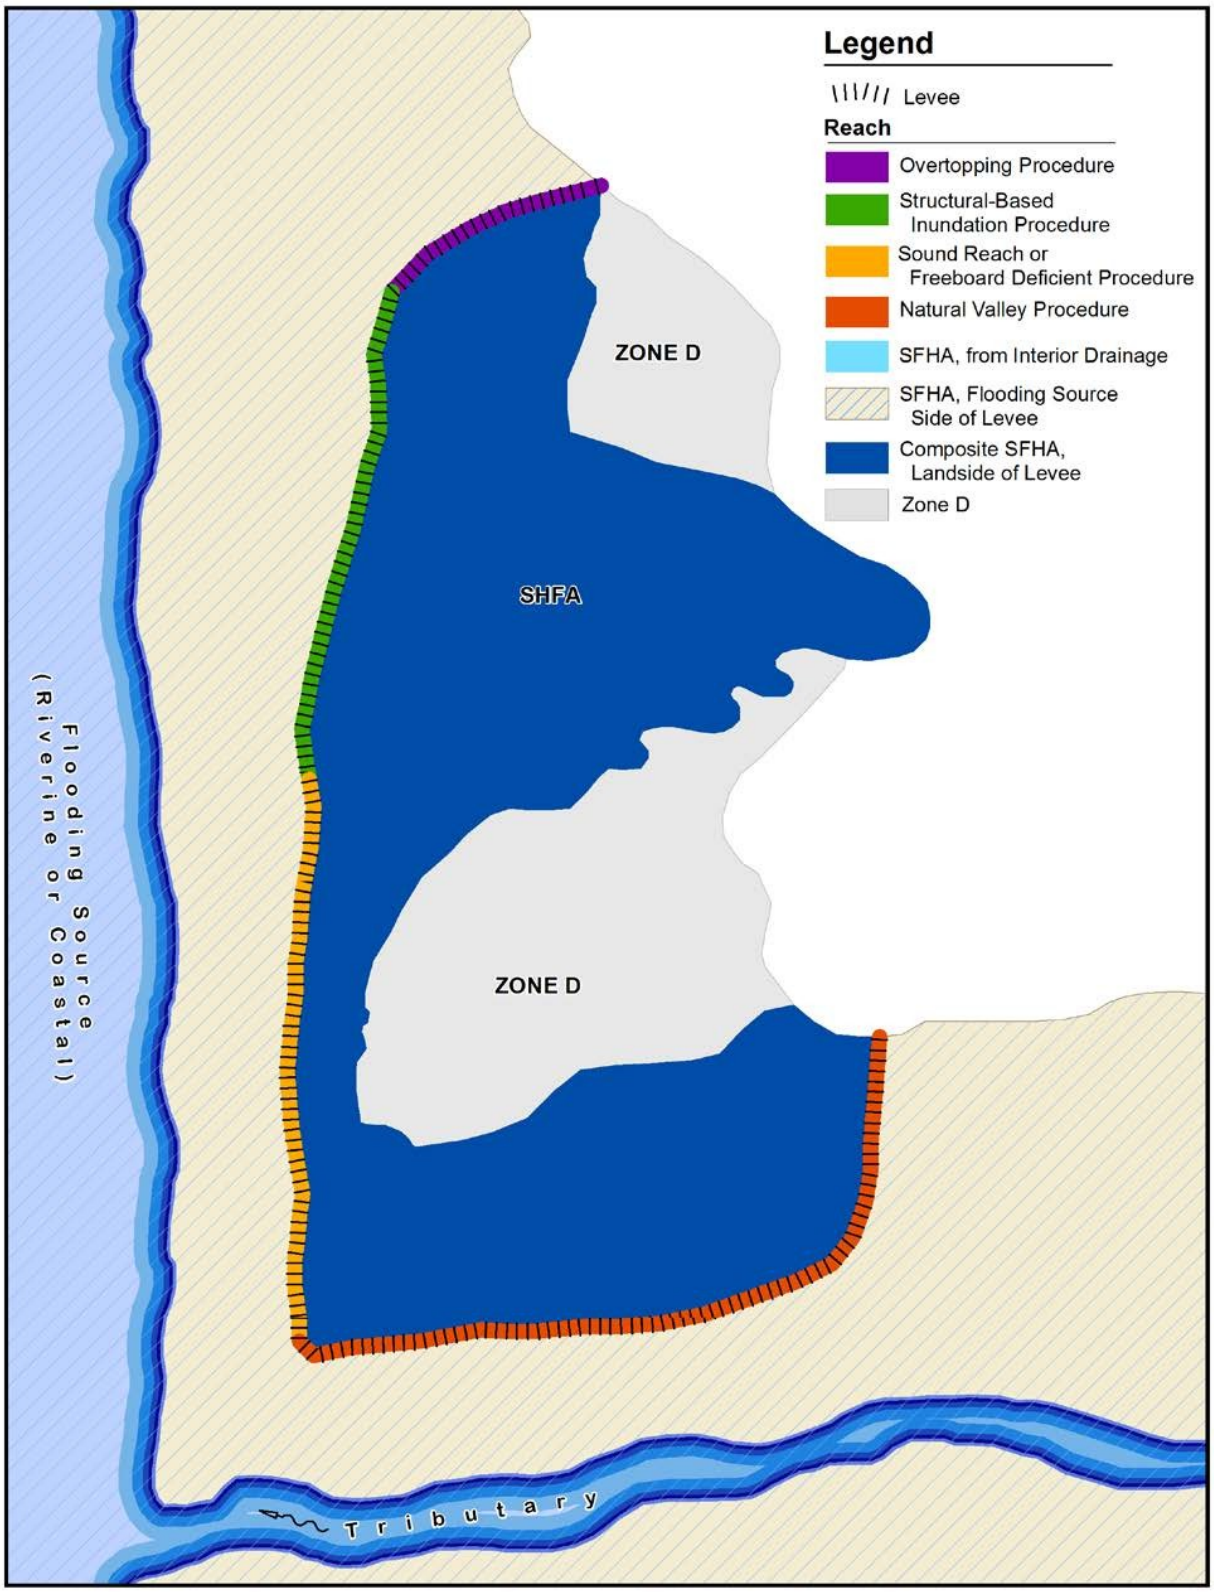

Figure 38: Composite Mapping of Flood Hazards for the Levee System

When the Structural-Based Inundation Procedure is used, the SFHA for that levee reach will be a composite of each independently analyzed breach location. The resulting floodplain from the analysis of a Structural-Based Inundation reach must reflect the fact that a breach could occur at any location along the reach. To achieve this, it may be acceptable for the assigned Project Team member to extrapolate breach analysis results to areas that were not analyzed separately. This will most often occur in situations where breach flows seek a flow path or storage area that is not directly adjacent to the levee. The final mapping will not reflect the analyzed breach locations, however; the final mapping will reflect the composite flood hazards resulting from all breach analyses conducted.

The input data requirements to map BFEs on the FIRM for the Overtopping and Structural-Based Inundation Procedures follow FEMA Guidance Document 31, Guidance for Flood Risk Analysis and Mapping: Mapping Base Flood Elevations on Flood Insurance Maps. The guidance document is accessible from the FEMA Guidelines and Standards for Flood Risk Analysis and Mapping webpage.

6.20.2 Flood Insurance Implication of Zone D Mapping

The NFIP defines Zone D as an area of possible, but undetermined, flood hazards. Historically, FEMA has used the Zone D designation in areas where a flood hazard analysis has not been completed.

When analyzing and mapping areas landward of non-accredited levee systems, FEMA will use Zone D to designate the possible 1-percent–annual-chance flood inundation on FIRMs. Zone D will supplement the SFHAs developed through the procedure(s) applied to individual levee reaches. The size and location of the Zone D areas will vary and be based on the results of the composite SFHA analysis that results from the Natural Valley Procedure. The natural valley analysis is hydraulically modeled for riverine levee reaches by retaining the topographic features of the levee in the model but allowing the discharge to flow on either side of the levee, assuming that the levee does not impede conveyance.

Flood insurance is available in Zone D; however, properties located in Zone D areas are not subject to the federally mandated flood insurance purchase requirement. Lenders may, however, require insurance coverage for properties located landward of levee systems regardless of the zone designation, as a condition of a loan, as part of their regular lending practices.

6.20.3 Floodplain Management Implications of Zone D Mapping

FEMA views the analysis of the non-accredited levee systems as an intermediate step in the possible process leading to full levee accreditation. Because Zone D is not considered an SFHA, SFHA regulations do not apply. Floodplain management requirements are applied at the discretion of local officials as long as the community complies with the minimum standards of the NFIP regulations cited at 44 CFR 60.3(a).

FEMA will depict the Zone D area landward of the levee system on the FIRM with a different symbology than the traditional Zone D area. The differentiation between Zone D types will allow various stakeholders to identify Zone D areas landward of the levee system for use in determining flood insurance requirements, enforcing floodplain management and mitigation, and communicating risk.

If the community chooses to enforce elevation requirements in Zone D areas landward of the levee for new construction, local officials could require development to take place at a set height above grade, taking an approach similar to floodplain management in an SFHA with established BFEs. If requested, tools that FEMA would make available to communities to aid in the enforcement of elevation requirements include flood depth grids and WSELs derived from the Zone D natural valley analysis. These tools would provide flood depths and elevations to which a community could regulate new construction. The data could be provided to the community upon completion of the non-accredited levee analysis.

6.20.4 Guidance Regarding FIRM Graphic and Database Standards

This subsection presents guidance on how to depict flood hazard information associated with non-accredited flood-control structures. The Zone D flood hazard zone designation, with a zone subtype defined as "Area with Undetermined Flood Hazard Due to Non-Accredited Levee System" should be used for the Zone D flood hazard area on the landward side of the non-accredited levee. For FIRMs developed using the current standards, the Project Team will apply the detailed specifications summarized in FEMA FIRM Panel Technical Reference.

In addition, FIRMs prepared under these graphical specifications will include the following note inside the map body. The note should be placed in the proximity of the subject levee feature(s).

Note: This panel contains levees that have not been accredited and are therefore not shown as reducing the hazard from the base flood.

The modeling results for the natural valley analysis should also be stored in the regulatory FIRM database. The community can use the natural valley cross-section GIS data to assist in elevation determinations for the purpose of map amendments and revisions. Therefore, the modeling cross sections from the natural valley analysis must be included in the regulatory FIRM database S_XS feature class. As described in the FEMA FIRM Database Technical Reference, all cross sections used in the development of the effective hydraulic models shall be stored in the S_XS table, regardless of flood hazard zone depiction on the effective panel. The Zone D cross sections are provided as backup data, as such they shall be assigned a XS_LN_TYP field value of "NOT LETTERED, NOT MAPPED". The Zone D cross sections must be assigned an appropriate model identifier in the MODEL_ID field of the S_XS table, as well as an appropriate source citation in the SOURCE_CIT field, to provide a link between the natural valley model and the spatial data. In addition, the S_XS table must link to data in the L_XS_ELEV table. The L_XS_ELEV table is designed to store cross section information for all event types and levee scenarios. For more information about populating the S_XS and L_XS_ELEV tables see the FIRM Database Technical Reference.

The Technical References cited above are accessible from the FEMA Technical References webpage (https://www.fema.gov/media-library/assets/documents/34519).

6.21 Guidance Regarding Flood Insurance Study Report Standards

This subsection includes guidance on how to capture flood hazard information associated with a non-accredited flood-control structure in the Flood Insurance Study report.

6.21.1 Text

For flood hazard mapping projects performed using the current standards, the assigned Project Team member will need to add information to Table 5: Summary of Hydrologic and Hydraulic Analyses. The flooding source should be identified as <Streamname> (Landside of Levee Reach #) and extents should correspond to the extents of the levee reach. The methodology used to determine the Zone D area should also be included in the table. An example of this table with appropriate information included is provided in Table 5 below.

The Technical References cited above are accessible from the FEMA Technical References webpage (https://www.fema.gov/media-library/assets/documents/34519).

Table 5: Sample Summary of Hydrologic and Hydraulic Analyses Table Guidance Clarification Routing

Flooding Source	Study Limits		Hydrologic Model or Method Used	Hydraulic Model or Method Used	Date Analyses Completed	Flood Zone on FIRM	Special Considerations
	Downstream Limit	Upstream Limit					
Culvert Creek (Landside of Levee Reach 1)	Confluence with South Fork Inundation River	1.3 miles upstream of confluence of Ripple Creek	Scaled Stream Gage Hydrograph	FLO-2D v. 2009.06	3/31//2012	AE	Modeling using the Structural-Based Inundation Procedure
Culvert Creek (Landside of Levee Reach 2)	1.3 miles upstream of confluence of Ripple Creek	0.5 miles upstream of confluence of Ripple Creek	Scaled Stream Gage Hydrograph	HEC- RAS 4.0	3/31//2012	AE	Modeling using the Natural Valley Procedure
Culvert Creek (Landside of Levee)	Confluence with South Fork Inundation River	0.5 miles upstream of confluence of Ripple Creek	Log Pearson Type III Frequency Analysis	HEC- RAS 4.0	3/31//2012	D	Modeling using the Natural Valley Procedure

Additional text is needed in Section 4.4 of the FIS when the Freeboard Deficient approach is used, and when Zone D is used. When Freeboard Deficient approach is used, the Project Team shall include the following text:

> "Please note that the **Levee System Name** meets the structural standards of 44 CFR 65.10 except lacking adequate freeboard. The flood hazard area landward for the levee system is mapped as Zone D per the freeboard deficient approach under FEMA's analysis and mapping procedures for non-accredited levee systems. The Zone D flood hazard area was determined based on a natural valley analysis of the **Flooding Source Name**.

When Zone D from an analysis and mapping procedure is used, the Project Team shall include the following text:

> In Zone D areas, floodplain management requirements are applied at the discretion of local officials as long as the community complies with the minimum standards of the National Flood Insurance Program (NFIP) regulations cited at 44 CFR 60.3(a). FEMA will depict the Zone D area landward of the levee system on the FIRM with a different symbology than the traditional Zone D area. The differentiation between Zone D symbology will allow various stakeholders to identify Zone D areas landward of the levee system for use in determining flood insurance requirements, enforcing floodplain management and mitigation, and communicating risk. For additional information regarding floodplain management requirements within Zone D areas, please consult with the local floodplain administrator for these communities. There is water surface elevation information available for these Zone D areas for communities use, as referenced in the Zone D Fact Sheets:
>
> - Understanding Zone D for Levees: "Areas of Undetermined Flood Hazards" https://www.fema.gov/sites/default/files/2020-08/fema_understanding-zone-D-levees.pdf
>
> - Modeling and Mapping Non-Accredited Levees: Understanding the Zone D Designation https://www.fema.gov/media-library-data/5b0ef91fd61d29eb3d4be72a47d6f140/508_LAMP_FS_ZoneD.pdf.

6.21.2 Floodway Data Table

The Floodway Data Table will show the elevations and surcharges based on the With Levee run. However, if applicable, the Floodway Data Table also will include the following footnote to alert future users that may modify the regulatory floodway:

> *The floodway limits on the non-leveed side of the flooding source are determined from the Natural Valley analysis.*

6.22 Documentation

For levee reaches analyzed and mapped using the Structural-Based Inundation Procedure, the Project Team will document levee breach location, parameters, and description of the methods used to determine this data. The Project Team also will document any historic breach data or other data used to support various procedures and decisions that were available.

The Project Team is to include documentation, such as reports submitted to satisfy the standards of 44 CFR 65.10, except for survey data for each reach, in the General Folder of the Hydraulics Data Capture Standards submission. See the FEMA Data Capture Technical Reference for more information on levee documentation in the Hydraulics task.

6.23 Review Procedures

FEMA Regional Offices may determine that the review for mapping non-accredited levees should be conducted through the regional support staff of FEMA's Risk MAP providers. Decisions made

during the process should be coordinated with the entity performing the independent Quality Assurance/Quality Control (QA/QC) review.

Submittals must include backup data and supporting information for all calculations, in case a more detailed review is required. A more detailed review must be coordinated with FEMA Headquarters.

The Project Team independent QA/QC reviewer will verify that all components use the same flooding elevations and conditions, and that the entire levee system (if a system consists of different segments) is considered in the submittal.

6.23.1 Reviewing Data Required to Apply Different Procedures

FEMA will review the submittal in accordance with Chapter 4 of this document. Due to the complexity and uniqueness of each coastal levee, the FEMA Project Officer or designee will coordinate and consult with FEMA Headquarters for all levees affected by coastal forces.

To verify that a submittal meets the overtopping analysis standard, the Project Team member assigned to perform an independent QA/QC review will verify that the submission includes documentation supporting two main items.

1. The documentation shows that no appreciable erosion of the levee crest, toe, embankment, or foundation occurs during the overtopping of the base flood event because of currents or waves.
2. The documentation indicates that the anticipated erosion will not result in structural failure (i.e., breach of the levee, directly or indirectly, through loss of embankment material due to erosive forces or the reduction of the seepage path or piping and subsequent instability).

The Project Team member assigned to perform the independent QA/QC review will verify that the submission includes a discussion of the items to consider as discussed in this guidance document and why they may or may not apply.

6.23.2 Reviewing Modeling and Mapping for Non-Accredited Levees

All hydraulic analyses, hydrologic analyses, and floodplain mapping submitted performed by the Project Team will be reviewed to verify that they satisfy FEMA standards. All data and documentation submitted to satisfy the standards of 44 CFR 65.10 will be reviewed per the criteria in Chapter 4.

For reaches modeled using the Structural-based Inundation Procedure, the Project Team member assigned to perform the independent QA/QC review will focus on verifying the following:

- The resulting SFHA does not indicate where individual breaches were located.
- The analysis reflects that the levee reach could breach at any location within the reach.
- How the submitter determined that additional breach locations were not required is documented.
- The breach parameters chosen fall within the historic ranges for the size, location, flooding source type, and soil type of the levee.

- The resulting SFHA reasonably reflects the composite results of all breach analyses.

7.0 Non-Levee Reaches and Non-Levee Features

Physical manmade features that were not designed and constructed as levees may exist near or within flood-prone areas, and these features may impact the conveyance of floodwaters. Levee systems may tie into these manmade features, whose existence and performance are necessary for excluding floodwaters from the levee-impacted area. In this case, these features are referred to as "non-levee reaches" in this document. Alternately, these features may exist independent of a levee system, but still may inadvertently impact floodwater conveyance; those features are referred to as "non-levee features" in this guidance document.

In either case, these features may be represented on effective FIRMs as reducing flood hazards and must be reconsidered when a new Flood Risk Project is initiated so that FEMA appropriately analyzes and maps the flood hazards that may be impacted by these features. For non-levee reaches that are part of or tie into a levee system for which the levee owner is seeking accreditation, the owner must provide documentation and certified data to FEMA demonstrating that the entire levee system meets the requirements of 44 CFR 65.10. If this requirement cannot be met, FEMA will analyze the levee system and map the levee-impacted area in accordance with FEMA's levee analysis and mapping procedures for non-accredited levee systems (refer to Chapter 6 of this document). To demonstrate that a non-levee feature impacts the conveyance of floodwaters, detailed data and engineering analyses must be provided to FEMA and certified by a registered P.E. in accordance with sound engineering practice. If an entity seeks accreditation for a non-levee feature, that entity must demonstrate that the feature meets the requirements of 44 CFR 65.10.

Previous FEMA mapping procedure documents (including Procedure Memorandum No. 51, dated February 27, 2009, which has been superseded by this document) used the term "non-levee embankments" to describe some of these types of features. Although this term is not used in this document, roadway and railroad embankments are examples of physical manmade features that are not typically designed and constructed to function as a levee system or other flood-control structure. However, these features may inadvertently represent flood hazard reduction or other impacts to the conveyance of floodwaters on current effective FIRMs, and as such, may indicate a lesser flood hazard and corresponding risk than what may actually exist in areas near these structures. Thus, it is important to understand the impact each feature may have on the flooding source to appropriately analyze and map the corresponding flood hazard in these areas.

It should also be noted that FHWA issued a memorandum on September 10, 2008, titled Highway Embankments versus Levees, and other Flood Control Structures, to their field offices and State Departments of Transportation (DOTs), emphasizing that most highway embankments are not designed and constructed to perform as a levee system or other flood-control structure. This memorandum also highlighted the distinctions between highway embankments, levee systems, and other flood-control structures; clarified the FHWA role with respect to flood control; and acknowledged that communities may have incorrectly assumed that these structures provide some level of flood hazard reduction.

This chapter provides clarity on the appropriate classification and subsequent data considerations, analysis, and mapping requirements for physical manmade features that are not designed and constructed as levee systems. In addition, guidance is provided that emphasizes the importance of coordination with communities to understand the location and impacts of these features to appropriately analyze and map the flood hazards in these areas.

7.1 Non-Levee Reach

Non-levee reaches are considered a form of manmade high ground that a levee system ties into and whose existence and performance is necessary for excluding floodwaters from the levee-impacted area. USACE also refers to these types of structures as “non-project segments.” To demonstrate that non-levee reaches meet the requirements of 44 CFR 65.10, they must be evaluated based on their current condition to determine eligibility for accreditation of the entire levee system of which they are a part. Coordination with communities and the owners of the non-levee reaches is essential to identify these features, appropriately analyze and map the flood hazards associated with these non-levee reaches, and to provide communities with information and tools to help them communicate flood risk and mitigation opportunities in these areas. Figure 39 provides an example of a non-levee reach.

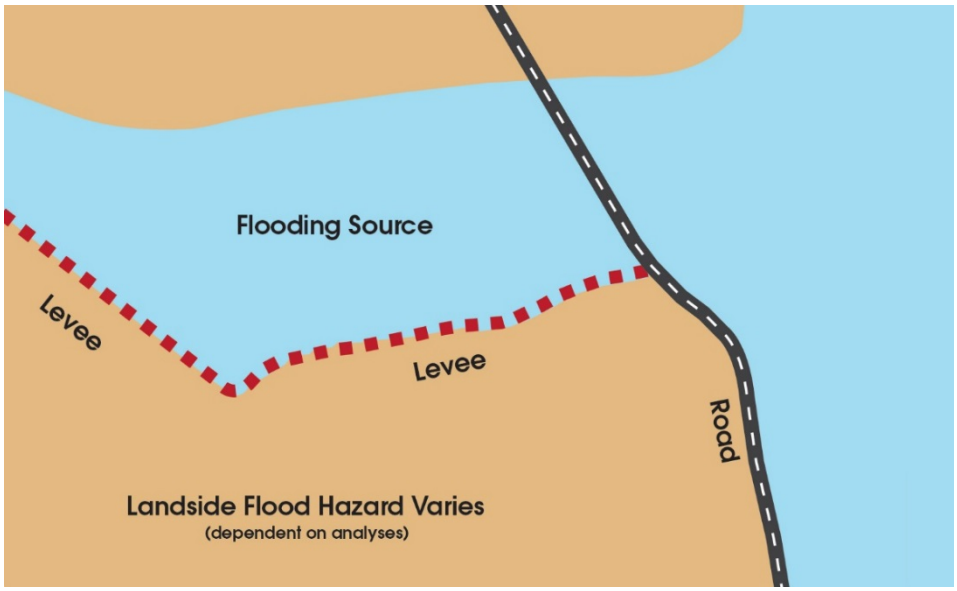

Figure 39: Non-Levee Reach

7.2 Non-Levee Features

A non-levee feature is considered a physical feature that is not designed, constructed, operated, or maintained as a flood-control structure, but may inadvertently confine flow during some flood events. These features may encroach on the floodplain but are not connected to any existing levee system and do not meet the definition of a levee system. They may include roadway and railroad embankments, canals, berms, retaining walls, seawalls, and other features, which involve placing fill or other material within flood-prone areas and which may impact the conveyance of floodwaters in these areas.

These features carry an inherent risk and may have inadvertently been represented as providing flood hazard reduction on a FIRM. Therefore, it is important to fully understand the impact of these features to identify the appropriate flood hazards in these areas. Coordination with communities and the owners of these non-levee features, when applicable, is essential to identify, analyze, and map the flood hazards associated with these non-levee features, and to provide communities with information and tools to help them communicate flood risk and mitigation opportunities in these areas. Figure 40 provides an example of a non-levee feature.

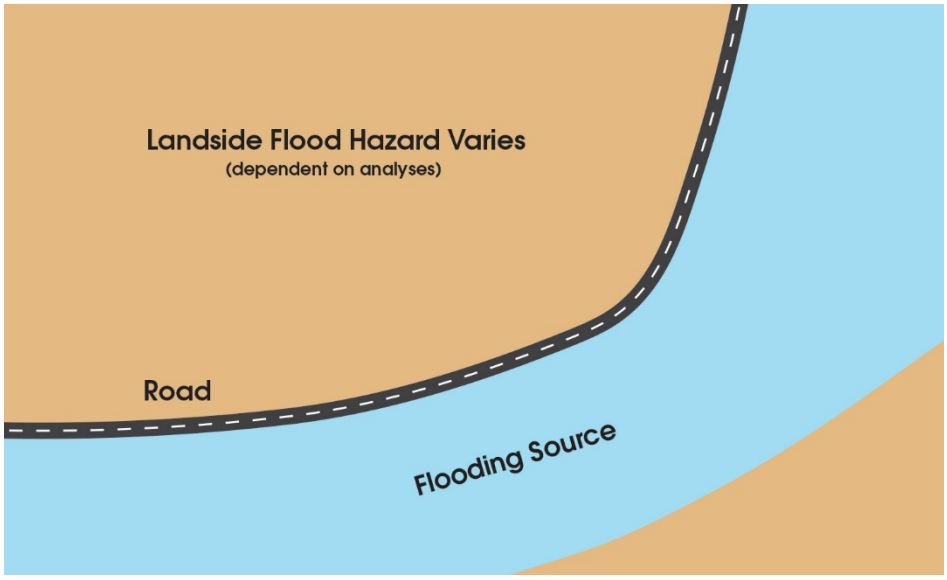

Figure 40: Non-Levee Feature

The flood hazard on the landside of most non-levee features will be analyzed and mapped as not providing base flood hazard reduction. If an entity seeks accreditation for a non-levee feature, that entity must demonstrate that the feature meets the requirements of 44 CFR 65.10. To demonstrate that a non-levee feature impacts the conveyance of floodwaters, detailed data and engineering analyses must be provided to FEMA and certified by a registered P.E. in accordance with sound engineering practice.

FEMA has documented several best practices that use various acceptable approaches for modeling and mapping of non-levee features based on standard engineering practice. Individuals should coordinate with the FEMA Regional Office or FEMA Headquarters to discuss flood hazard analysis and mapping requirements that may be appropriate for particular non-levee features.

7.3 Communication of Risk

To appropriately analyze and map the flood hazards in impacted areas, FEMA will coordinate with communities during the Discovery Phase of a Flood Risk Project, and throughout the project lifecycle as necessary, to understand the location and impacts of non-levee reaches and non-levee features. Where physical manmade features that were not designed and constructed as levee systems exist near or within flood-prone areas, the impact of these features on the conveyance of floodwaters may change over time. The current effective FIRMs may inadvertently represent these features as providing flood hazard reduction or other impacts to the conveyance of floodwaters, and as such, may indicate a lesser flood hazard and corresponding risk than what may actually exist in areas near these structures.

Communities and property owners may not be fully aware of the risk associated with these non-levee features. Therefore, coordination with local stakeholders is essential to identify, analyze, and map the flood hazards associated with these non-levee features to provide relevant information and tools to help them understand their flood risk and mitigation opportunities in these areas.

8.0 FEMA and Other Federal Agency Coordination

OFAs may have a role in working with FEMA to develop levee-related policy, identify flood risk, conduct mitigation, and outreach activities, or provide data to inform the FEMA flood hazard mapping program for areas impacted by levees.

8.1 USACE

Though FEMA and USACE have different roles and responsibilities related to levee systems, both agencies have complementary objectives related to reducing risk to life and property and communicating flood hazards and risks. FEMA has information and data to supplement USACE Levee Safety Program activities. Conversely, information from USACE Levee Safety Program activities will supplement FEMA activities. Jointly, FEMA and USACE will align activities, information, and messaging related to levee systems to improve public awareness of flood risk. Main areas of engagement between the USACE Levee Safety Program and FEMA flood hazard identification activities are further described below.

- Leveraging Data: Both USACE and FEMA perform activities using best available information to include, but not limited to, mapping, hydrologic, hydraulic, and coastal modeling, and infrastructure condition. Early coordination of both USACE Levee Safety Program and FEMA activities will result in finding opportunities to share and leverage information that will benefit both agencies. Both agencies will use the NLD as the main database of information for both the NFIP and USACE Levee Safety Program.
- Mapping Levee-Related Flood Hazards for the NFIP: Communities or parties seeking recognition of a levee system as reducing the base flood hazard on FIRMs, also referred to as levee accreditation, must provide data and documentation in accordance with 44 CFR 65.10. USACE and FEMA have agreed to specific cases when information collected by USACE through their Levee Safety Program will inform some or all requirements for levee accreditation, and that is further specified in Chapter 4 of this document. In cases when information collected by USACE informs some of the requirements for levee accreditation, the communities or parties seeking accreditation will have to provide information to fulfill the remaining requirements. Because some of the USACE Levee Safety Program activities are conducted on a levee segment basis, caution should be taken to ensure information is used, presented, and considered collectively on a levee system basis when using USACE information to inform a levee accreditation decision. Examples of USACE information include inspections and risk assessments.
- Risk Communication: Both USACE and FEMA have the objective to increase public awareness as related to flood risk. In areas with levee systems, USACE typically engages directly with levee sponsors and FEMA engages directly with community officials. Coordination of these relationships helps improve public awareness and effective risk communication. USACE and FEMA will coordinate to ensure consistent messages related to risk, levee condition, and mapping/modeling efforts. One example is the importance for FEMA to verify and maintain NFIP-related information in the NLD and ensure that information is accurate and includes the appropriate messaging for levee sponsors and communities.

- Engagement Processes: FEMA will develop engagement processes with the appropriate USACE District and Division offices and will identify processes to ensure information is exchanged in the most efficient, beneficial, and meaningful way possible. Engagement processes should include cross-walking FEMA mapping efforts with USACE Levee Safety Program activities and planning for joint engagement with levee sponsors and communities where most efficient and effective.
- Routine Coordination: Each step in the FEMA KDP process asks if there is a levee system in the project footprint, and if so, is there an ongoing or recently completed USACE project or analysis that may impact how the levee is represented on the FIRM? This question is asked at each KDP to serve as a reminder that levee system conditions and data change over time, so it is important for FEMA to routinely coordinate with USACE to ensure the most current information is taken into consideration throughout the Risk MAP project lifecycle.
- Disaster Recovery: Under the Stafford Act, FEMA may direct USACE (as an operating agent for the U.S. Department of Defense) to use its available resources to provide assistance in case of a major disaster or emergency declaration by the President. In areas with levee systems, USACE levee safety information and expertise contribute to the recovery efforts.
- Coordination of Agency Processes and Policies: USACE and FEMA will coordinate on the development and implementation of levee-related policy, including coordination of acceptable technical standards related to operation and maintenance plans, emergency preparedness plans, and levee design, construction, and rehabilitation activities.

Additional OFAs may have levee system-related data and may interact directly with communities and levee owners. If during the Flood Risk Project lifecycle, a Project Team determines that OFAs have information about a particular levee system, FEMA will contact the agencies to determine what useful input may be available. Some potential items to consider from different agencies are:

- USBR: USBR works in the western states and is involved with levees, canals, and dams. They may have useful data, such as construction drawings and O&M procedures.
- USGS: USGS is a primary source of hydrologic data used to determine flows and potential water-surface profiles related to the levees.
- NOAA: NOAA is a primary source for coastal data used to evaluate impacts on levees in coastal areas.
- NRCS: NRCS has historical involvement with some agricultural levees; drawings and design data may be available.
- United States Section of the International Boundary and Water Commission (IBWC) (Rio Grande River): IBWC has worked on, and been responsible for the design, construction, operation, and maintenance of, some levees along the Rio Grande River. However, they rarely have data related to interior drainage, so coordination with the local communities will still be required.

- U.S. Department of Agriculture (USDA): FEMA has developed some talking points related to agricultural levees, potential impacts on crop insurance, and potential coordination with local USDA staff that might be useful. (See Table 6.)
- Federal Energy Regulatory Commission (FERC): Some dam or levee structures may be owned by hydropower companies and regulated by FERC, whose efforts are usually related to safety and security, so the availability of information may be restricted.
- U.S. Environmental Protection Agency (EPA): As part of levee accreditation process, there may be a need for the levee owner to coordinate with EPA related to local environmental requirements.
- U.S. Department of Housing and Urban Development (HUD): FEMA and HUD sometimes coordinate outreach activities, so coordination with the FEMA Regional Office will be necessary to determine if there is a need for further coordination.
- The U.S. Fish and Wildlife Service (USFWS): Similar to EPA, there may be circumstances where FEMA needs to contact USFWS. For instance, dealing with vegetation on levees to provide shade to control water temperatures related for salmon in the northwest.

Any other Federal or State agency that owns or operates a levee system would likely be a source of useful information.

Table 6: Crop Insurance, Flood Insurance Rate Maps, and Levees

Internal Talking Points for FEMA/Contract Staff Attending Community Levee Meetings

Background	Stakeholders in rural areas have asked FEMA staff about what impact Flood Insurance Rate Maps (FIRMs) and levee accreditation status may have on their crop insurance policy rates.
Crop Insurance Rate Determinations	• The USDA Risk Management Agency (RMA) makes crop insurance determinations. • Crop insurance premiums are determined by county and crop type on a case-by-case basis. RMA focuses on **actual flood events**, not a statistical 1-percent-annual-chance flood event. The determinations by RMA are based on gage data and USACE flood-related data, satellite imagery, aerial photography, and soil maps, to indicate the severity and/or extent of flooding. In addition, the timing of past floods compared to crop type is used to determine premiums.
FEMA/USACE Related Resources	• **FIRMs:** FIRMs are not used by RMA for making crop insurance premium determinations. The base flood event on a FIRM is a statistical prediction of a flood, not a depiction of an actual event. • **NLD:** RMA does, on occasion, use this data source. It provides information on levee location, condition, and the "Leveed Area.".

Role of Levees	• **Levee Impact:** Levees may have positive or negative impacts on cropland.
	  ○ Positive: May reduce risk of flooding.
	  ○ Negative: Interior drainage can back up on the landside of the levee, causing crop damage – especially if pump stations, flap gates, etc. are not properly operated and maintained. An actual levee breach will

	impact crop insurance premiums. RMA monitors levee repairs with USACE and/or local levee districts.
Summary	• FEMA does not determine crop insurance premiums. • Flood hazard boundaries shown on FIRMs have no impact on the USDA crop insurance program related to premium rating. • A levee may be considered by RMA on a case-by-case basis. It could provide flood risk reduction, but it could also make interior drainage worse. • Data collected for FEMA's flood hazard mapping studies or accreditation per 44 CFR 65.10 may be provided to RMA to assist in rating information, but FEMA will only do so when requested by stakeholders or RMA staff.

The need for additional information on engagement with OFAs should be coordinated through the FEMA Regional Office.

FEMA

Reports & Data

Critical Facility

For some activities and facilities, even a slight chance of flooding is too great a threat. Typical critical facilities include hospitals, fire stations, police stations, storage of critical records, and similar facilities. These facilities should be given special consideration when formulating regulatory alternatives and floodplain management plans. A critical facility should not be located in a floodplain if at all possible. If a critical facility must be located in a floodplain it should be provided a higher level of protection so that it can continue to function and provide services after the flood. Communities should develop emergency plans to continue to provide these services during the flood.

Under Executive Order 11988, Floodplain Management, Federal agencies funding and/or permitting critical facilities are required to avoid the 0.2 percent (500-year) floodplain or protect the facilities to the 0.2 percent chance flood level.

Whether you are in a high risk zone or not, you may need flood insurance (https://www.fema.gov/national-flood-insurance-program) because most homeowners insurance doesn't cover flood damage. If you live in an area with low or moderate flood risk, you are 5 times more likely to experience flood than a fire in your home over the next 30 years. For many, a National Flood Insurance Program's flood insurance policy could cost less than $400 per year. Call your insurance agent today and protect what you've built.

Learn more about steps you can take (https://www.fema.gov/what-mitigation) to reduce flood risk damage.

Technical Guidance Manual for Stormwater Quality Measures - New Developmer

This page is to communicate information on the revisions to Technical Guidance Manual for Stormwater Co this page is updated, please send a request to David Laak (David.Laak@ventura.org) with "TGM Stakeholder

[NEW] TGM Errata Update 2018 Version

The 2015 TGM Errata Update was updated in 2018 to correct minor errors and unintentional omissions. Du to the evolving nature of stormwater quality management, the TGM may continue to be updated to correct errors, to incorporate new and innovative control measures, or to add the Hydromodification Control Plan.

Section 1: Introduction/Lay Description

1.1 Overview

This volume presents the Urban Water Management Plan 2020 (Plan) for the City of San Buenaventura and its Ventura Water Department (the City or Ventura Water) service area, which includes the City boundary as well as unincorporated areas within the City's Sphere of Influence. This chapter describes the general purpose of the Plan, discusses Plan implementation, and provides general information about the service area characteristics. A list of acronyms and abbreviations is provided at the end of the table of contents.

1.2 Purpose

An Urban Water Management Plan (UWMP) is a planning tool that generally guides the actions of water management agencies. It provides managers and the public with a broad perspective on a number of water supply issues. It is not a substitute for project-specific planning documents, nor was it intended to be when mandated by the State Legislature. For example, the Legislature mandated that a plan includes a section which "describes the opportunities for exchanges or water transfers on a short-term or long-term basis." (California Urban Water Management Planning Act, Article 2, Section 10630(d).) The identification of such opportunities, and the inclusion of those opportunities in a general water service reliability analysis, neither commits a water management agency to pursue a particular water exchange/transfer opportunity, nor precludes a water management agency from exploring exchange/transfer opportunities not identified in the plan. When specific projects are chosen to be implemented, detailed project plans are developed, environmental analysis, if required, is prepared, and financial and operational plans are detailed.

In short, this Plan is a management tool, providing a framework for action, but not functioning as a detailed project development or action. It is important that this Plan be viewed as a long-term, general planning document, rather than as an exact blueprint for supply and demand management. Water management in California is not a matter of certainty and planning projections may change in response to a number of factors. From this perspective, it is appropriate to look at the Plan as a general planning framework, not a specific action plan. It is an effort to generally answer a series of planning questions including:

- What are the potential sources of supply and what is the reasonable probable yield from them?
- What is the probable demand, given a reasonable set of assumptions about growth and implementation of good water management practices?
- How well do supply and demand figures match up, assuming that the various probable supplies will be pursued by the implementing agency?

Using these "framework" questions and resulting answers, the implementing agency will pursue feasible and cost-effective options and opportunities to meet demands.

The California Urban Water Management Planning Act (Act) requires preparation of a plan that:

- Accomplishes water supply planning over a 20-year period in five-year increments (the City is going beyond the requirements of the Act by developing a plan which spans 25 years.)

- Identifies and quantifies adequate water supplies, including recycled water, for existing and future demands, in normal, single-dry, and multiple-dry years.

- Implements conservation and efficient use of urban water supplies.

State legislation, Senate Bill 7 of Special Extended Session 7 (SBX7-7) was signed into law in November 2009, which calls for progress towards a 20 percent reduction in per capita water use statewide by 2020. The legislation mandated each urban retail supplier develop and report an interim 2015 water use target, their baseline daily per capita use and 2020 compliance daily per capita use, along with the basis for determining those estimates. This UWMP reports on Ventura Water's final progress in meeting the SBX7-7 targets.

In short, the Plan answers the question: *Will there be enough water for the area served by the City in future years, and what mix of programs should be explored for making this water available?*

It is the stated goal of the City to deliver a reliable and high-quality water supply for customers, even during dry periods. The analysis in this Plan documents that it is necessary for the City to implement planned water supply projects in order to meet normal and dry-year demands. In the near term (2020-2026) until such time as planned supplies come on-line, anticipated supplies in a multiple-dry year are insufficient and the City would have to call on existing customers to undertake extraordinary conservation. After planned water supplies are available the potential for a water supply shortage is lessened.

1.2.1 Relationship to the City's Annual Comprehensive Water Resources Report

The Urban Water Management Plan is required by the California State Water Code. The UWMP is a long-term planning tool that provides water purveyors and their customers a broad perspective on water supply issues over a 20-year period (this plan goes further and looks at 25 years). The UWMP is a management tool, providing the framework for action but not functioning as a detailed project development plan.

In 2013 the City Council directed Ventura Water and the Community Development Department to work together to develop a short-term balance of water supply and demand. The result of this collaboration is the annual Comprehensive Water Resources Report (CWRR). The CWRR specifically focuses on water demand of approved (entitled) projects only. The CWRR focuses on a short timeframe and on near-term demand changes. The CWRR estimates demands from approved projects whereas the UWMP estimates demands from population projections. In the latest 2021 CWRR the estimated demand of approved projects would be fully vested by year 2025. This latest CWRR estimates demand to the year 2030 using a growth rate of 0.54 percent (the Department of Finance historical data for City of San Buenaventura population growth).

Understanding and monitoring water supply and demand is essential to planning for and managing a stable and reliable water system to support the community and economic growth. The City's supply and demand play an important role and dramatically influence the planning for, development of, and investment of significant dollars in capital improvements, maintaining current water supply and investing in new water supplies. Therefore, the annual CWRR is an important tool that the City utilizes to update the City's annual projected water supply and demand.

1.3 Structure and Organization of the Plan

This plan is organized as follows:

- Introduction
- Water Demand
  - SBX7-7 Reduction
- Water Resources
- Recycled Water
- Water Quality
- Reliability Planning
- Demand Management Measures
- References
- Appendices

Appendix A contains a checklist documenting how this UWMP meets the requirements of the Urban Water Management Planning Act and SBX7-7. Starting with the 2015 UWMP, urban water suppliers are required to report and submit information in standardized tables developed by the Department of Water Resources (DWR). These standardized tables are provided as Appendix B of this document.

This plan is being prepared for Ventura Water, a Department of the City, and is an individual rather than Regional Urban Water Management Plan. Data provided in this plan are reported in calendar years rather than fiscal years. To the extent possible water volumes are reported in acre-feet (AF). Tables 1-1 and 1-2 document the structure of this plan.

TABLE 1-1
PUBLIC WATER SYSTEM COVERED BY THIS PLAN

Public Water System Number	Public Water System Name	# of Municipal Connections 2020	Volume of Water Supplied 2020 (AF)*
CA5610017	City of San Buenaventura Water Department	32,285	13,556

Notes: *Includes all metered consumption

☑	Acre Feet (AF)
☐	Million Gallons (MG)
☐	Hundred Cubic Feet (CCF)

1.4 Implementation of the Plan

Preparation of UWMP 2020 was coordinated by Ventura Water. Ventura Water staff met with and coordinated the development of the UWMP with various City Departments as well as the Ventura Water Commission. Based on the City's 2005 General Plan, Sustainable Infrastructure, Policy 5B, Ventura Water has adopted guidelines which require that adequate water supply, system capacities, and wastewater collection system and treatment capacities are available before new development can be approved by the Community Development Department. This subsection provides the cooperative framework within which the Plan will be implemented including agency coordination, public outreach, and resources maximization.

1.4.1 Joint Preparation of the Plan

The UWMP Act requires a water supplier to coordinate the preparation of its plan with other appropriate agencies in the area. This includes other water suppliers that share a common source, water management agencies, and relevant public agencies, to the extent practicable. Various agencies are involved in supplying water to the City or having jurisdiction over a portion of the water resources. This section briefly discusses each one. Table 1-3 summarizes the efforts the City has taken to include the various City Departments, agencies, and citizens in the preparation of this document.

TABLE 1-3
AGENCY COORDINATION SUMMARY [PENDING]

	Participated in UWMP Development	Commented on the Draft	Attended Public Meetings	Contacted for Assistance	Received Copy of Draft	Sent Notice of Intention to Adopt	Not Involved / No Information

Mound Basin Groundwater Sustainability Agency						X	
Ojai Valley Sanitary District						X	
Ventura County Local Agency Formation Commission						X	

- **City of San Buenaventura Community Development Department**
  The Community Development Department is responsible for planning and zoning, economic development, housing and redevelopment for the City of San Buenaventura. The department works with various city departments, city commissions, and the City Council to guide and provide advice regarding growth in the city. The Community Development Department works with the community and City Council to create and document the vision for land use in the city and the various policies and regulations applicable to redevelopment and new development. The Community Development Department was consulted regarding changes in population and economic activity in the service area which may affect water demands.

- **City of Oxnard Public Water Works Division**
  The City of Oxnard is a neighboring jurisdiction that was contacted to be given the opportunity to provide input to the 2020 UWMP.

- **Ventura County Resource Management Agency**
  Ventura Water serves a very minor amount of water to connections outside the City limits within the unincorporated County. These connections must meet the City's policy for water connections (Municipal Code Section 22.110.055). Ventura Water notified the County Resource Management Agency of the UWMP Update and the methods by which the County could provide input to the plan. In December 2015, the County of Ventura started an update to its General Plan; Ventura Water participated in the General Plan Update. The 2040 General Plan Update was adopted in October of 2020.

- **Fox Canyon Groundwater Management Agency (FCGMA)**
  The FCGMA was created by state legislation in 1982 to manage local groundwater basins and resources in a manner to reduce overdraft of the Oxnard Plain and stop seawater intrusion. A major goal of the FCGMA is to regulate and reduce future extractions of groundwater from the Oxnard Plain aquifers, in order to operate the basin at a safe yield. Ventura Water withdraws water from the Oxnard Plain Groundwater Basin and is subject to the management policies of the FCGMA. Ventura Water notified FCGMA of the 2020 UWMP Update and the methods by which the FCGMA could provide input to the plan.

- **United Water Conservation District (United)**
  United is primarily a groundwater recharger and a wholesale purveyor in central Ventura County and does not provide any water directly to the City. However, all of the City's groundwater wells within the Mound, Oxnard Plain, and Santa Paula groundwater basins are within United's boundaries and are subject to United's semi-annual extraction fees. Ventura Water notified United of the 2020 UWMP Update and the methods by which United could provide input to the plan.

- **Santa Paula Basin Technical Advisory Committee (TAC)**
  The Santa Paula Basin is subject to a stipulated judgment and is managed by the Santa Paula Basin Technical Advisory Committee (TAC) with equal representation from United Water Conservation District (UWCD), the Santa Paula Basin Pumpers Association (SPBPA), and Ventura Water. The TAC is charged with establishing a program to "monitor conditions in the basin, including but not necessarily limited to verification of future pumping amounts, measurements of groundwater levels, estimates of inflow to

and outflow from the basin, increases and decreases in groundwater storage, and analyses of groundwater quality." The Judgment also allows for the development of a management plan for the operation of the basin and empowers the TAC to determine the safe yield of the basin. Ventura Water notified the Santa Paula Basin TAC of the 2020 UWMP Update and the methods by which the TAC could provide input to the plan.

- **Upper Ventura River Groundwater Agency (UVRGA)**
  The Upper Ventura River Groundwater Agency was created in 2016 by several agencies using a Joint Powers Agreement. In 2017, the Agency became a Groundwater Sustainability Agency. The UVRGA is managed by a seven-member Board of Directors – five public agency directors, including Ventura Water, and two stakeholder directors that represent environmental and agricultural interests.[1]

  Ventura Water notified the UVRGA of the 2020 UWMP Update and the methods by which the UVRGA could provide input to the plan.

- **Mound Basin Groundwater Sustainability Agency (MBGSA)**
  The Mound Basin Groundwater Sustainability Agency (MBGSA) was created in 2017 by several agencies using a Joint Power Agreement and became a Groundwater Sustainability Agency in June 2017. The MBGSA includes United Water Conservation District, the County of Ventura, the City of San Buenaventura, the Mound Basin Ag Water Group (agricultural stakeholder), and an environmental stakeholder. "United is authorized under the California Water Code to conduct water resource investigations, acquire water rights, build facilities to store and recharge water, construct wells and pipelines for water deliveries, commence actions involving water rights and water use, and prevent interference with or diminution of stream/river flows and their associated natural subterranean supply of water (California Water Code, section 74500 et al.). The County of Ventura exercises water management and land use authority on land overlying the entire county including Fillmore and Piru Basins. The City of [San Buenaventura] is a local municipality that exercises water supply, water management, and land use authority within the city's boundaries."[2]

  Ventura Water notified the MBGSA of the 2020 UWMP Update and the methods by which the MBGSA could provide input to the plan.

- **Ojai Valley Sanitary District (OVSD)**
  The OVSD is an adjacent district that collects and treats wastewater from a population of approximately 20,000 across the City of Ojai, the unincorporated Ojai Valley, and the north Ventura Avenue area. Ventura Water notified the OVSD of the 2020 UWMP Update and the methods by which the OVSD could provide input to the plan.

- **Ventura County Local Agency Formation Commission**
  The Ventura Local Agency Formation Commission (LAFCo) was formed and operates under the provisions of state law, specifically what is now known as the Cortese-Knox-

[1] Upper Ventura River Groundwater Agency, https://uvrgroundwater.org/about/
[2] Mound Basin Groundwater Sustainability Agency, https://www.moundbasingsa.org/about-us/

Hertzberg Local Government Reorganization Act of 2000 (California Government Code Section 56000 et seq.). State law provides for LAFCos to be formed as independent agencies in each county in California. LAFCos implement state law requirements and state and local policies relating to boundary changes for cities and most special districts, including spheres of influence, incorporations, annexations, reorganizations and other changes of organization. In this capacity the Ventura LAFCo is the boundary agency for cities and most special districts in Ventura County.

All LAFCos have general objectives such as to, 1) encourage the orderly formation and expansion of local government agencies, 2) preserve agricultural land resources, 3) discourage urban sprawl. Additionally, all LAFCos have authorities such as to, 1) regulate boundary changes, 2) establish spheres of influence – the probable physical boundaries and service area of a city or special district, and 3) conduct reviews of public services and special studies, 4) initiate special district consolidations or dissolutions, and 5) act on out of agency service agreements between public agencies and between public agencies and private parties.[3]

Ventura Water notified the LAFCo of the 2020 UWMP Update and the methods by which the LAFCo could provide input to the plan.

- **Casitas Municipal Water District (Casitas)**
  Casitas is a wholesaler of treated surface water from Lake Casitas to the City under the terms and conditions of the 2017 Agreement. Casitas' service area is in Western Ventura County, including the City of Ojai, Upper Ojai, the Ventura River Valley area, the City of Ventura to Mills Road, and the Rincon and beach area to the ocean and Santa Barbara County Line. Casitas supplies water to 60,000-70,000 people and to hundreds of farms. The western portion of the City of San Buenaventura is within the Casitas service area[4]. Ventura Water notified Casitas of the 2020 UWMP Update and the methods by which Casitas could provide input to the Plan.

1.4.2 Plan Adoption

The City began preparation of this Plan in August 2020. A draft of the plan was presented to and reviewed by the City Water Commission on April 27 and May 25, 2021. The final draft of the Plan was adopted by the City Council on [TBD] by Resolution No. 2021-[TBD] (Appendix C) and submitted to DWR within 30 days of City Council approval. This plan includes all information necessary to meet the requirements of Water Conservation Act of 2009 (Wat. Code, §§ 10608.12-10608.64) and the Urban Water Management Planning Act (Wat. Code, §§ 10610-10656). Additionally, the plan has also been submitted to all appropriate entities and made available for public review per the requirements of the Urban Water Management Planning Act.

[3] Ventura Local Agency Formation Commission, https://www.ventura.lafco.ca.gov/about-us-2/
[4] Casitas Municipal Water District, https://www.casitaswater.org/about-us/about-casitas-water

1.4.3 Public Outreach

Urban water agencies preparing plans are required to hold a public hearing on the UWMP prior to its adoption. In response to these requirements, a public hearing was conducted [TBD] by the City to receive public comment and input on the UWMP. Table 1-4 presents a timeline for public participation during the development of the Plan. A copy of the public outreach materials, including paid advertisements, newsletter covers, website postings, and invitation letters are attached in Appendix D.

TABLE 1-4
PUBLIC PARTICIPATION TIMELINE

Public Workshops and Hearings	Date	Public Participation Task
UWMP Status Update	March 23, 2021	Presentation at City Water Commission
UWMP Administrative Draft	April 27, 2021	Presentation at City Water Commission
UWMP Final Draft, Final Draft Available for Public Review	May 25, 2021	Presentation to City Water Commission, Available for Public Review
Public Hearing and Adoption	June 14, 2021	City Council Meeting

1.5 System Description

The City is located 62 miles north of Los Angeles and 30 miles south of Santa Barbara along the California coastline. The City's planning area is bounded by the Ventura River on the west, Foster Park on the north, Franklin Barranca and the Santa Clara River to the east, with the Pacific Ocean as the southern boundary. The total planning area encompasses approximately 40 square miles. The City water service area is shown on Figure 1-1.

The City developed as a result of the ninth and last mission founded in California by Father Junipero Serra in 1782. In 1866, the City incorporated an area of about one square mile around the original Mission San Buenaventura. Since that time, the City has grown. An estimated population of 113,500[5] is currently supplied water from the City's water system. This includes several unincorporated County areas, such as the upper North Ventura Avenue area to the north and developing areas east of the City boundary.

The City Charter provides for a City Council-Manager form of government. A seven-member City Council is elected at large for four-year terms, with the Mayor selected by the City Council for a two-year term. The City of San Buenaventura Water Commission was formed in 2015 to provide policy guidance on water and wastewater issues to City Council as representatives of the community and Ventura Water customers. The Water Commission reviews and makes advisory recommendations regarding water rates, water resources infrastructure projects in the

[5] This population estimate is based the 2021 Comprehensive Water Resources Report. Current (2020) population as estimated by the DWR Population Tool (described in section 2.3.20) is 115,815. The calculation of gallons per capita per day targets in section 2.3 uses the population as estimated by the DWR Population Tool.

five-year capital improvement program, the integrated water resources management plan, water supply options, the Urban Water Management Plan approval process, a water dedication and in-lieu fee requirement, and other water resource issues.

The Spanish Fathers of Mission San Buenaventura developed the first water system for the City. It consisted of an aqueduct (now abandoned) to convey water from the Ventura River, near San Antonio Creek, to a reservoir located behind the Mission.

During subsequent development around the Mission, additional groundwater was obtained from wells in the Ventura and Santa Clara River basins. Water facilities were developed and operated for the City by several individuals and companies over the period of 1869 to 1923. In 1923, the City acquired the water system, along with its water rights from the Ventura River, from the Southern California Edison Company and assumed the responsibility of providing water to City residents. In years following, the City developed additional sources of surface and groundwater, including wells and improvements to the surface water diversion from the Ventura River. Also, since 1960, the City has purchased surface water from Casitas Municipal Water District to supplement its water supplies. As the City boundaries expanded east, the City took over other water systems such as Mound Water Company and Saticoy Water Company. As development occurs on the east side of the City, additional groundwater facilities have also been completed to meet increasing demands.

Currently, the City's water system serves approximately 32,285 water service connections, which includes the population of the City plus some additional areas outside the City boundaries. The western portion of the City is within the Casitas Municipal Water District service area. The mid and eastern portion of the City are within United Water Conservation District's boundaries. Water service is provided to all residential, commercial, industrial and irrigation customers, including fire protection users.

The City water system is a geographically complex system of 16 pressure zones, 10 active wells, 19 booster stations, approximately 385 miles of pipelines ranging from 4-inches to 36-inches in diameter, and a total storage capacity of approximately 52 million gallons (MG) in 27 tanks and reservoirs. The system delivers water from sea level to a maximum elevation of over 1,000 feet. The City operates three purification facilities, including one membrane filtration treatment plant for surface water sources on the west side of the City, and two iron/manganese removal treatment plants for groundwater sources on the east side (City of San Buenaventura 2011). The City also maintains and operates the Ventura Water Reclamation Facility for wastewater treatment and reclamation. See Section 4 for further description of the Reclamation Facility.

1.6 Land Use

The City's 2005 General Plan is the basis for understanding land use in the Ventura Water service area. Each year as part of the CWRR, Ventura Water updates the land use information from the 2005 General Plan to reflect projects built in the past year. Table 1-5 provides a summary of land uses in the water service area as estimated through 2020. Based on the "build-out" envisioned in the 2005 General Plan Table 1-5 provides a summary of remaining developable land.

TABLE 1-5
SUMMARY EXISTING LAND USE – DECEMBER 2020

Land Use	As of December 2020	Potential Remaining Development
Residential (units)	3,230	5,088
Retail (sf)	447,026	794,351
Office (sf)	474,521	738,693
Industrial (sf)	1,191,437	1,043,696
Hotel (sf)	25,360	504,640

1.7 Population

The City water service area is an established community comprised primarily of residential areas with opportunities for infill development. Large commercial and industrial areas exist along Main Street, Harbor Boulevard, Telephone Road, Ventura Avenue, Telegraph Road and Victoria Avenue (City of San Buenaventura 2011). In 2005, the City adopted the 2005 Ventura General Plan to redirect future growth toward 'Infill First' with an emphasis on encouraging more dense development of housing alongside commercial uses in the above-mentioned commercial corridors, as well as Johnson Drive and Wells Road. The City's estimated population growth for the water service area is shown in Table 1-6. The population numbers reflect both the population within the City limits as well as the minor number of customers in the unincorporated county.

Future projections for areas within the City reflect a 0.54 percent annual growth rate through 2030[6]. From 2030-2045, the future projections for areas within the City also reflect a 0.54 percent annual growth rate[7]. Population estimates were extrapolated to fit five-year increments. It is important to note that these figures are not intended to represent support for, nor reflect any commitment to, this level of growth. Rather, it is to provide a safe margin in planning for long-term water improvements that might be needed given the amount of growth that could be allowed under the City's 2005 updated General Plan as assessed in the certified EIR.

TABLE 1-6
POPULATION PROJECTIONS

	2020	2025	2030	2035	2040	2045

[7] Maximum historic growth rate that the City of Ventura saw prior to Thomas Fire (2010-2018).

1.8 Social, Economic and Demographic Factors Affecting Water Management

The following information has been taken from the 2019 Local Profile for San Buenaventura prepared by the Southern California Association of Governments. The 2019 Local Profile was the most recent information that could be obtained for the City.

Between 2000 and 2018, the total population of the City of San Buenaventura increased by 10,353 to 111,269. During this 18-year period, the city's population growth rate was lower than the Ventura County rate. The city, while the County seat, makes up 13 percent of the total population of Ventura County. Between 2000 and 2018, the 55-64 age group experienced the largest increase in share of the city's population, growing from 8.3 to 13.7 percent. Conversely the 35-54 age group declined as percent of the population from 32 to 25.6 percent. In this same timeframe, the share of Hispanic population in the city increased from 24.3 percent to 35.4 percent and the share of Non-Hispanic White population in the city decreased from 68.1 percent to 56.3 percent. The share of Non-Hispanic Asian population in the city increased modestly, from 2.9 percent to 3.7 percent as did the share of the Non-Hispanic Black population (1.3 percent to 1.4 percent). There was a modest decline in the share of Non-Hispanic American Indian or Alaska Native population in the city from 0.6 percent to 0.4 percent.

Between 2000 and 2018, the total number of households in the City of San Buenaventura increased by 3,299 units, or 8.6 percent, lower than the county growth rate of 12.5 percent. As of 2018 the City's average household size was 2.6, lower than the county average of 3.1. Seventy seven percent of all city households had 3 people or fewer and about 29 percent of the households were single-person households. A small percentage of households, about 10 percent had 5 people or more. Between 2000 and 2018, homeownership rates decreased and the share of renters increased. In 2018 approximately 46.2 percent of households were renters and 53.8 owners. In 2018, the median home sales price in the city was $583,000, the same as that in the county overall.

The housing stock consist primarily of single-family detached homes (approximately 89%) with limited amounts of multi-family housing (approximately 11%).

The majority of the City of San Buenaventura housing stock pre-dates 1980 as shown in Table 1-7.

TABLE 1-7
HOUSING CHARACTERISTICS CITY OF SAN BUENAVENTURA (2018)

Housing Age	Percent of Housing Stock	Housing Age	Percent of Housing Stock
1939 and earlier	7.6	1980 to 1989	13.2
1940 to 1949	4.2	1990 to 1999	8.0
1950 to 1959	15.2	2000 to 2009	8.5
1960 to 1969	22.4	2010 to 2018	4
1970 to 1979	20.0		

About 34 percent of households earned less than $50,000 annually and approximately 33 percent of households earned $100,000 or more. From 2000 to 2018, median household income increased by $20,693, from $52,166 to $72,859. Housing costs are significant portion of income. In 2018 housing costs accounted for an average of 34.7 percent of total household income for renters and an average of 22.5 percent of total household income for homeowners.

Data shows a decreasing number of jobs in the city from 2007 to 2018 with a significant decline in jobs in the manufacturing sector (17.2 percent) and construction sector (declined of 37.7 percent), and a modest decline in administrative and professional jobs (6.1 percent).

1.9 Climate

The City has a climate that is similar to a Mediterranean coastal city. That is, the winters are cool, and the summers are mild. The average temperature range is in the 70s and it is uncommon for the temperature to drop below freezing. The area has an average rainfall of approximately 13.5 inches. Table 1-8 shows the average annual climate information by month.

TABLE 1-8
ANNUAL CLIMATE INFORMATION

	Jan	Feb	Mar	Apr	May	Jun
Standard Monthly Average ETo (in)	2.5	2.6	3.7	4.6	5.1	5.3

Evapotranspiration (ETo) data from Station #152 in the City of San Buenaventura as provided on the CIMIS website database at www.cimis.water.ca.gov for the period of record from January 2000 to November 2020.
The average rainfall data is from Ventura County Watershed Protection District's web site for Station 066E, https://www.vcwatershed.net/hydrodata/php/getstations.php?dataset=rain_hour&order=site_id, for the period October 2005 to September 2020.
The average temperature figures are from the Western Regional Climate Center web site at www.wrcc.dri.edu for Station 049285 VENTURA.

1.10 Potential Effects of Climate Change

A topic of growing concern for water planners and managers is climate change and the potential impacts it could have on California's future water supplies. Climate change models have predicted that potential effects from climatic changes will result in increased temperature, early snow melt, and a rise in sea level.

In the 2013 update of the *DWR California Water Plan*, the implications of future climate conditions are evaluated. These changing hydrological conditions could affect future planning efforts, which are typically based on historic conditions. The *California Water Plan* identifies the following probable impacts due to changes in temperature and precipitation:

- More winter runoff and less spring/summer runoff due to warmer temperatures.

- Greater extremes in flooding and droughts.
- Greater water demand for irrigation and landscape water due to increased temperatures and their impacts on plant water needs.
- Increased sea level rise, increased threat of coastal flooding, and salt water intrusion into coastal groundwater aquifers.

In the 2019 report of *Projected Changes in Ventura County Climate* (Oakley et. al. 2019), the implications of future climate conditions are evaluated. These changing hydrological conditions could affect future planning efforts, which are typically based on historic conditions. The report of *Projected Changes in Ventura County Climate* identifies the following probable impacts due to changes in temperature, precipitation, evaporative demand, and other variables:

- Increases in both maximum and minimum temperatures and heat extremes.
- More intense precipitation focused during the winter season.
- Increased evapotranspiration.
- Increased drought risk.
- Potential for longer wildfire season with more ignitions as population growth continues.
- Reduced marine stratus.
- Reduction in Sierra Nevada snowpack.
- Longer duration and more intense atmospheric rivers.

Even without population changes, water demand could increase. Precipitation and temperature influence water demand for outdoor landscaping and irrigated agriculture. It is typical that about half of the water used by residential development is for outdoor use and therefore it is assumed that outdoor water use is a large component of the City of San Buenaventura water demands.

1.11 Fundamental Findings of the Urban Water Management Plan

It is the stated goal of the City to deliver a reliable and high quality water supply for customers, even during dry periods. The analysis in this Plan documents that it is necessary for the City to implement planned water supply projects in order to meet normal and dry-year demands. In the near term (2021 to 2024) until such time as planned supplies come on-line, there is little buffer between supplies and demands and it may be necessary for the City to call on existing customers to undertake extraordinary conservation should drought persist. After planned water supplies are available the potential for a water supply shortage is lessened.

Section 2: Water Demands

2.1 Overview

This chapter describes historic and current water usage and the methodology used to project future demands within the City's service area. The City's water system provides potable water to residential, commercial, institutional, industrial, and irrigation customers. Untreated water is provided to an industrial user and a few irrigation customers in the vicinity of the raw water pipeline system in the North Ventura Avenue area. Recycled water is provided for general irrigation of two golf courses, a City park, and landscape irrigation along the existing distribution alignment. The City's water use sectors are described below[8].

- **Residential Sector**
  The residential sector of the City is comprised of single and multi-family residential customers. The residential accounts serve apartment and condominium complexes as well as mobile home parks. The residential sector represents approximately 66 percent of the City's total water consumption. Within the residential sector, single family accounts make up approximately 61 percent of the total residential demand.

- **Commercial/Institutional Sector**
  The City contains several different types of commercial/institutional customers including retail establishments, office buildings, laundries, schools, prisons, hospitals nursing homes, churches, and campgrounds. The City includes several tourist-driven businesses such as hotels, which benefit from the high volume of tourist traffic. Currently, there are approximately 2,700 commercial/institutional accounts. The commercial/institutional sector accounts for approximately 25 percent of the City's water consumption.

- **Industrial Sector**
  The City contains a relatively small industrial sector including manufacturing. Currently, there are two industrial accounts. The industrial sector utilizes approximately less than one percent of the City's water demand.

- **Landscape Irrigation Sector**
  This sector only includes water usage from dedicated irrigation meters. Water used for irrigation on properties without separate irrigation meters is included in other sectors. The City's landscape metered uses include assessment districts, contract parks, City parks, cemeteries, median strips, golf courses and other irrigation areas. The landscape irrigation sector accounts for approximately three and a half percent of the City's water consumption.

[8] Account quantities and consumption percentages are derived from the 2020 Water Deliveries Report.

- **Other Uses**
  The City has other miscellaneous usage, which include the following: fireline consumption, temporary construction meters, fire training. This usage is estimated to be one percent of the total water demand.

- **Recycled Water**
  The City provides recycled water delivered from the City's Water Reclamation Facility for general irrigation at two golf courses, a City park, and landscape irrigation along the existing distribution alignment. This usage accounts for approximately four percent of total water demand[9].

- **Water Loss**
  Water loss is estimated based on a comparison of billing records (consumption) versus production records and does not include recycled water in this report. Based on City historical information it is estimated at approximately 5 to 10 percent of total produced water since 2005. The City of San Buenaventura reviewed apparent loss (loss due to meter inaccuracies) and real loss (due to leaks or theft) from 2015 to 2019 using AWWA's Water Audit Software. The software estimates water loss average of 7.61%. The 2019 Water Loss Audit Report is provided in Appendix E.

2.2 Historical Water Use

Currently the City has approximately 32,285 service connections serving 113,500 people[10]. All service connections are metered. Water consumption within the City has decreased in recent years. The annual per capita usage from 1940 to 1970 averaged about 277 gallons per capita per day (GPCD). In the period 1985 through 1989, the annual per capita use averaged about 196 GPCD. In the period 1994 through 2010, the per capita figure dropped to an average of 166 GPCD. This decrease in per capita consumption is the result of plumbing code changes such as low flow fixtures and low water consuming appliances in some existing and all new housing; and an active water conservation program adopted by the City in 1975 and further strengthened with regulations in 1990. As detailed in Section 2.4, the baseline GPCD for the 10-year period was 176 and the baseline GPCD for the 5-year period was 167. In 2015 the reported GPCD was 159. In 2020 the reported GPCD was 104.

[9] Recycled water consumption percentage from the 2021 CWRR.

[10] This population estimate is based on input from the 2021 Comprehensive Water Resources Report. Current (2020) population as estimated by the DWR Population Tool (described in section 2.3.20) 115,815. Calculations for compliance with gpcd targets uses the DWR Population Tool estimates.

TABLE 2-1
DEMANDS - ACTUAL 2020

Use Type	Level of Treatment	Volume (AF)
Single family	Drinking Water	5,489
Multi-family	Drinking Water	3,443
Commercial/Institutional	Drinking Water	3,219
Irrigation	Drinking Water, Untreated	380
Other	Drinking Water	160
Water Loss[1]	Drinking Water, Untreated	865
Total Potable and Untreated Water Production [2]		*13,556*
Recycled Water	Recycled Water	564
	Total Water Demand	**14,120**

Notes:
2020 demand from billing records = 12,746 AF (excludes recycled water)
2020 production from production report = 13,556 AF (excludes recycled water)
[1] 2020 production minus 2020 demand (excludes recycled water)
[2] From production source report (does not include recycled water)

2.3 Water Loss

Distribution system water losses is the physical potable water losses from the pressurized water distribution system. Ventura Water estimates its distribution system loss using the American Water Works Association Method, annually. As required, Ventura Water reports information on water losses annually to the State. Table 2-2 reports water loss estimates 2015 to 2019. The Water Loss Audit Reports submitted to the State for these years is provided in Appendix E.

TABLE 2-2
ESTIMATED WATER LOSS 2015-2019

Period Covered	Estimated Water Loss (AF) (volume of apparent and real water losses)	% of Water Produced
Calendar Year 2015	1,449	10.1
Calendar Year 2016	933	6.8
Calendar Year 2017	1,122	8.4
Calendar Year 2018	620	4.6
Calendar Year 2019	1,079	8.3

At the current time a water loss standard has not been adopted by the State of California. Future UWMPs prepared by Ventura Water will report on compliance with any State water loss standards.

2.4 Existing and Target Per Capita Water Use

As required by SB X7-7, the Water Conservation Bill of 2009, this section identifies the water use targets in 2015 and 2020 to demonstrate a 20% reduction in per capita water use by 2020. Included are calculations of the baseline gross water use expressed as per capita daily water use (gallons per capita per day, or GPCD), baseline and target population, and year 2020 urban

water use target. This section includes a description of how Ventura Water calculated its baseline and target per capita water demands, in accordance with Method No. 1 described in "*Methodologies for Calculating Baseline and Compliance Urban Per Capita Water Use*" (DWR Methodologies, 2011). Ventura Water has completed the SB X7-7 Verification Form, attached as Appendix F, and summarized in Tables 2-4 and 2-5 of this chapter.

2.4.1 Base Daily Per Capita Water Use for SBX7-7 Reduction

Two baseline periods are to be determined during the calculation of the base daily per capita water use. The first is a continuous 10- to 15-year period used to calculate baseline per capita use, and the second is a continuous 5-year period used to determine whether the 2020 per capita water use target meets the legislation's minimum water use reduction requirements of at least a 5% reduction per capita water use.

The legislation allows the first continuous baseline period to increase from a 10-year to a 15-year base period if the amount of recycled water delivered in 2008 was 10% or greater of total water demand. Ventura Water's recycled water use in 2008 did not meet 10% or greater total water demand; therefore, under the legislation, Ventura Water may not use anything greater than a 10-year base period.

Tables 2-3 and 2-4 summarize the Base Daily Water Use calculation for Ventura Water. As a part of the SB X7-7 requirements, both a 10-year base period and a 5-year base period were selected in the 2010 UWMP, and were not able to be altered after having been selected. Years 1995 to 2004 were selected for calculation of the 10-year base period while years 2003 to 2007 were selected for calculation of the 5-year base period.

TABLE 2-3
BASELINE PERIOD RANGES

Baseline	Parameter	Value	Units
10 to 15 year baseline period	2008 total water deliveries	19,234	AFY
	2008 total volume of delivered recycled water	625	AFY
	2008 recycled water as a percent of total deliveries	3.2 %	Percent
	Number of years in baseline period[1]	10	Years
	Year beginning baseline period range	1995	-
	Year ending baseline period range[2]	2004	-
5 year baseline period	Number of years in baseline period	5	Years
	Year beginning baseline period range	2003	-
	Year ending baseline period range[3]	2007	-

Notes:
Data is for Calendar Year

[1]If the 2008 recycled water percent is less than 10 percent, then the first baseline period is a contiguous 10-year period. If the amount of recycled water delivered in 2007 is 10 percent or greater, the first baseline period is a contiguous 10 to 15 year period.

[2] The ending year must be between December 31, 2004 and December 31, 2010.

[3] The ending year must be between December 31, 2007 and December 31, 2010.

As shown in the top portion of Table 2-4, the Ventura Water Baseline GPCD is estimated to be 176. As shown in the second portion of Table 2-4, the Ventura Water 5-year Baseline GPCD is 167.

TABLE 2-4
GALLONS PER CAPITA PER DAY

	Year	Service Area Population [1]	Gross Water Use (AFY)	Gross Water Use (million gallons a day)	Daily Per Capita Water Use (GPCD)
10 to 15 Year Baseline GPCD					
1	1995	96,334	18,060	16.12	167
2	1996	97,634	19,489	17.40	178

	2020	115,815	13,557	12.1	**104**

[1] From DWR Population Tool

2.4.2 2015 and 2020 Targets

The year 2020 target was established in the 2015 UWMP. To assist the reader, this section reviews how the 2020 Target was established.

The City chose to meet SBX7-7 targets as an individual agency rather than as part of a regional alliance. Ventura Water selected Method 3, achieving 95% of the applicable South Coast Hydrologic Region target. The South Coast Hydrologic Region target is 149 GPCD, 95% of this target is 142 GPCD.

The Maximum Allowable GPCD is 95 percent of the 5-year Baseline GPCD or 159. The Compliance Water Use Target, under Method 3 (142 GPCD) is less than the Maximum Allowable GPCD and therefore no adjustments to the Compliance Water Use Target were needed. This makes Ventura Water's Compliance (2020) Water Use Target 142 GPCD. These calculations are summarized in Table 2-5.

Table 2-5
2020 Target Compliance

10-yr Base Daily Per Capita Water Use (GPCD)	2020 Target Calculated with Method 3 (95% of South Coast Hydrologic Region)	5-yr Base Daily Per Capita Water Use (GPCD)	Maximum Allowed GPCD Target (95% of 5-Year Base)	Confirmed 2020 Target (GPCD)
176	142	167	159	142

2.4.3 Achievement of Target

As shown in Table 2-6, the Ventura Water is in compliance with the 2020 Target, with an actual 2020 GPCD of 104. DWR has allowed for optional adjustments to the 2020 GPCD, including extraordinary events, economic adjustments, and weather normalization. Ventura Water made no such adjustments to the 2020 GPCD, as compliance was achieved without these factors.

Table 2-6
SBX7-7 2020 Compliance

Actual 2020 GPCD	Target GPCD	Total Adjustments	Adjusted 2020 GPCD	Did Supplier Achieve Targeted Reduction for 2020?
104	142	0	142	Yes

2.5 Projected Water Use

The earliest codes and standards for water fixtures and appliances came from the Federal Energy Policy Act of 1992 (taking effect in 1994). Besides Department of Energy (DOE) regulations, the codes and standards affecting water use in California are contained primarily in the CALGreen Building Code, the California Plumbing Code, California Water Code, and California Appliance Efficiency Standards.

The 2010 California Green Building Standards Code (CALGreen) set new standards for the flow rates of plumbing fixtures in new construction. The 2010 CalGreen Code went into effect on January 1, 2011 and its purpose was to reduce indoor water use in California buildings by 20%. The code also required that for buildings over 50,000 sq ft separate water meters be provided (e.g., required that multifamily dwellings have individual rather than master meters). The 2010 CalGreen Building code did have some provisions for outdoor water use including a

requirement for automatic irrigation systems utilizing weather and/or soil moisture-based irrigation controllers and a requirement that new landscapes of a given size conform to water budgets of either local ordinance or the State Model Water Efficient Landscape.

Updates to the CALGreen code in 2012 expanded the scope of CALGreen to include not just new construction but additions and alterations to buildings.

During the 2015-2016 drought, CALGreen was amended to require that new landscapes of a given size conform to water budgets of either local ordinance or the State Model Water Efficient Landscape, whichever is more stringent. In addition, the Code was amended to further reduce the allowable flow rate of faucets and urinals. Subsequently the CALGreen Code was revised to reduce the maximum flow rate of showerheads to align with Appliance Efficiency Regulations. This included a requirement that for all newly constructed residential developments, including hotels and motels, where disinfected tertiary recycled water was available from a municipal source, include provisions for potable water supply and a recycled water supply.

Starting January 1, 2017, California regulation required that upon sale, all single-family, multifamily, and commercial real property disclose all noncompliant plumbing fixtures. Effectively, as a condition of sale, all residential and commercial properties built prior to January 1, 1994, will need to replace all noncompliant plumbing fixtures with water conserving plumbing fixtures including toilets, shower heads, and faucets.

Unlike showerheads, faucets, and toilets, clothes washers are not covered by the California Plumbing Code, but rather regulated by the DOE. The current standards for residential clothes washers took effect in 2018. The standards, which were based on a consensus agreement between manufacturers and efficiency advocates, specify minimum energy and water efficiency levels. The metric for water efficiency is the integrated water factor (IWF), which is expressed in terms of gallons of water consumed per cubic foot of washer capacity. A lower IWF indicates better water efficiency. The standards specify an IWF of 6.5 for top-loading machines and 4.7 for front loading machines. Standard residential clothes washers have a capacity of approximately 4 cubic feet.

The table below summarizes appliance standards over time.

Fixture and Appliance Standards Over Time

	1975	1980	1992	2009	2011	2013	2016	2018
Shower (gpm)	3.5	2.5	2.5	2.5	2.0	2.0	2.0	1.8
Toilets (gpf)	5.0	3.6	1.6	1.6	1.28	1.28	1.28	1.28
Kitchen Faucet/ Lavatory Faucet (gpm)	2.5	2.5	2.5	2.2	1.8	1.8/1.5	1.8/1.2	1.8/1.2
Clothes Washers (gal/cycle/cubic ft)	15.0	15.0	15.0	9.5	9.5	9.5	9.5	6.5/4.7*

Data for 1975 to 2013 from Consol and California Homebuilding Foundation. 2014. Codes and Standards Research Report, California's Residential Indoor Water Use.
Data for 2016 and 2018 from Appliance-Standards.org.
*top loading machine/front-loading machine

The table above illustrates that there is limited water savings potential in new California homes; existing homes, particularly those built prior to 1980 represent a huge source of potential water savings. Conversely, the age of the housing stock is an indication of the affect that codes and

standards likely have on water demands. If the majority of the housing stock is older, the effect of the codes and standards is limited. If the growth rate of the service area is slow, the effect of codes and standards is also limited.

The City has approximately 42,000 housing units; 70% of which were built before 1980. Since 2014 it is estimated that certificates of occupancy have been issued for less than 1,600 housing units. This means new housing meeting the newest water efficiency standards makes up less than 4% of the residences. However, with rebate programs, natural replacement of old or malfunctioning appliances, retrofit upon resale, or remodels, some of the older housing is likely water efficient.

The water demands for this UWMP utilize water demand factors developed in April 2020, which were used in the 2021 CWRR. These water demand factors have been applied to the existing and anticipated land uses in the Ventura Water service area. The water demand factors looked at billing data for the City, for various uses, for the period 2013 through 2018, a water loss factor was applied to the raw factor, and a planning-level contingency factor was applied to account for variability due to weather and drought. The water demand factors capture changes in demand due to aggressive water conservation and codes and standards that have occurred over time. Because growth in the Ventura Water service area is minimal (approximately 0.54% a year) it is not necessary to apply a different water demand factor to new dwellings. Applying an optimistically "low" water demand factor on new development could skew demand trends when it is uncertain if (a) the development will truly occur and (b) the development will have a truly low water demand.

2.5.1 Normal Year

The normal/average year is a year in the historical sequence that most closely represents median runoff levels and patterns. Projected water demands in a normal year are shown in Table 2-7. Table 2-7 provides estimates of demands in each year from 2025 to 2045 assuming growth in the service area consistent with the City General Plan (see Section 1.6) and assuming water demand grows at a similar rate to population. Projections assume similar customer water use as occurred 2015 to 2019.

The water projections in Table 2-7 are based on the City's annual CWRR. The 2021 CWRR includes demand estimates based only on approved projects that would be fully vested by year 2025 and estimates demands to year 2030 using a growth rate of 0.54 percent. In addition, drought years are included in the baseline demand used in the CWRR. After year 2030 this UWMP assumes growth in demand of 0.54 percent. The projections in Table 2-7 assume a "normal" water year. In a normal water year, it is assumed that Drought Water Rates are no longer in effect and that various drought shortage restrictions are lifted. Demand in dry years is considered in the section below.

TABLE 2-7
PROJECTED WATER USE 2025 TO 2045 - NORMAL YEAR (AF)

Use Type	2025	2030	2035	2040	2045
Potable and Untreated Water Demand					
Single family	5,761	5,919	6,080	6,246	6,416
Multi-family	3,614	3,712	3,814	3,918	4,025
Commercial/Institutional/Industrial	3,378	3,471	3,565	3,663	3,763
Parks/Landscape/Irrigation	399	410	421	432	444
Other [a]	168	173	177	182	187
Water Loss [b]	908	933	958	984	1,011
Total Potable and Untreated Water Demand	*14,228*	*14,617*	*15,015*	*15,425*	*15,846*
Recycled Water	576	576	576	576	576
Total Water Demand	**14,804**	**15,193**	**15,591**	**16,001**	**16,422**

Notes:

a Other category includes authorized consumption for miscellaneous uses that do not fit the definition of the above (i.e., oil industry use, temporary construction water, and fire training.

b Water Loss assumed to grow at the same rate as water overall demands

2.5.2 Dry Years

2.5.3 Weather Effects on Water Usage

Historically, when the weather is hot and dry, water usage increases. The amount of increase varies according to the number of consecutive years of hot, dry weather and the conservation activities imposed. During cool-wet years, historical water usage has decreased to reflect less water usage for external landscaping.

California faces the prospect of significant water management challenges due to a variety of issues including regulatory restrictions, climate change, and population growth. Climate change is of special concern because of the range of possibilities and their potential impacts on water supplies. The most likely scenarios involve accelerated sea level rise and increased temperatures, which will shift more runoff to winter months. The other much-discussed climate scenario or impact is an increase in precipitation variability, with more extreme drought and flood events posing additional challenges to water managers[11].

However, the probability that water use will increase during dry conditions is countered by conservation actions, including drought rates, that may be implemented by Ventura Water, as has been done in the recent drought events. Over the past decade the water use per person (in GPCD) in the City's service area has seen a consistent decline. Ventura Water has experienced

[11] Final California Water Plan Update 2009 Integrated Water Management: Bulletin 160.

great success in water conservation after implementing multiple customer outreach and customer rebate programs and applying drought rates, as were first implemented in 2014 following a request for a 10 percent voluntary conservation by customers and a subsequent 20% mandatory conservation by customers. In 2015, drought rates were implemented. More information on Ventura Water's demand management programs can be found in Chapter 6 of this UWMP. Table 2-8 projects demands during dry years and it is assumed that demands will increase by 10% in dry periods (Table 2-7).

TABLE 2-8
PROJECTED WATER USE 2025 TO 2045 - DRY YEAR (AF)

Use Type	2025	2030	2035	2040	2045
Potable and Untreated Water Demand					
Single family	6,337	6,511	6,688	6,870	7,058
Multi-family	3,975	4,083	4,195	4,309	4,427
Commercial/Institutional/Industrial	3,716	3,818	3,922	4,029	4,139
Parks/Landscape/Irrigation	439	451	463	476	489
Other [a]	185	190	195	200	206
Water Loss [b]	999	1,026	1,054	1,083	1,112
Total Potable and Untreated Water Demand	*15,650*	*16,079*	*16,516*	*16,967*	*17,430*
Recycled Water	576	576	576	576	576
Total Water Demand	**16,226**	**16,655**	**17,092**	**17,543**	**18,006**

Notes:

a Other category includes authorized consumption for miscellaneous uses that do not fit the definition of the above (i.e., oil industry use, temporary construction water, and fire training.

b Water Loss assumed to grow at the same rate as water overall demands

2.6 Low Income Projected Water Demands

Senate Bill 1087 requires that water use projections of an UWMP include the projected water use for single-family and multi-family residential housing for lower income households as identified in the housing element of any city, county, or city and county in the service area of the supplier. The City of San Buenaventura last updated its Housing Element in September 2013 for the 2014-2021 5th cycle of Regional Housing Needs Assessment (RHNA). The City Housing Element projects that 44 percent of households to be low-income (extremely low/very low/low) (City of San Buenaventura 2013). Despite this, the Housing Element does not provide any information that can be used to develop trends to calculate the associated water demand specific to low -income households in the Ventura Water service area.

Table 2-9 makes an estimate of future low-income household water demands in the Ventura Water service area. Table 2-8 assumes a similar occurrence of low-income households in the water service area as in the City of San Buenaventura (i.e., 40 percent). These demands are included (and are not in addition to) the water demands described in Tables 2-7 and 2-8.

Ventura Water will not deny or condition approval of water services, or reduce the amount of services applied for by a proposed development that includes housing units affordable to lower income households unless one of the following occurs:

- The City specifically finds that it does not have sufficient water supply.
- The City is subject to a compliance order issued by the Division of Drinking Water Services that prohibits new water connections.
- The applicant has failed to agree to reasonable terms and conditions relating to the provision of services.
- The City finds it is not in compliance with the City's current Water Shortage Event Contingency Plan.

TABLE 2-9
PROJECTED WATER USE LOW INCOME HOUSEHOLDS (AF)

Water Use [a]	2025	2030	2035	2040	2045
Estimated Low-Income Household Water Use - Normal Year	4,125	4,238	4,353	4,472	4,594
Estimated Low-Income Household Water Use - Dry Years	4,537	4,662	4,788	4,919	5,053

Note:

a Assumes 44 percent all future households in Ventura Water service area qualify as "low" income per the definition provided in Senate Bill 1087.

Pursuant to Government Code Section 65589.7 the City is to grant priority for the provision of water and sewer services to proposed developments that include housing units affordable to lower income households.

Section 3: Water Resources

3.1 Overview

This section describes the water resources available to the City for the 25-year period covered by the Plan. Both currently available and planned supplies are discussed.

There are presently six distinct water sources providing water to the City water system.

- Casitas Municipal Water District (Casitas)
- Ventura River Foster Park Area (Foster Park)
- Mound Groundwater Basin (Mound Basin)
- Oxnard Plain Groundwater Basin (Oxnard Plain Basin)
- Santa Paula Groundwater Basin (Santa Paula Basin)
- Reclaimed water and reuse from the Ventura Water Reclamation Facility.

In addition, the City has a 10,000 AFY contract amount from the California State Water Project, which is not utilized within the City service area because currently there are no facilities to deliver the water to the City, but it is a planned supply (see Section 3.7.1 below).

3.1.1 Management of Supplies

The City operates its water supply system by utilizing a conjunctive use operating procedure. The procedure involves utilizing surface water (such as the Ventura River) during wet years, to the fullest extent possible, while letting groundwater sources rest. During dry years when the surface water source is reduced, the groundwater sources are pumped to meet demands.

Conjunctive use of the City's existing groundwater sources is limited by the requirement to maintain long-term production from the groundwater basins within their safe or operational yield. Conjunctive use of groundwater requires treatment and blending ratios to meet water quality goals.

Conjunctive use of potential future supply sources may include potable reuse or California State Water Project (SWP) water.

In the future, the City will continue delivering recycled water as occurs now (~576 AFY). The remainder of available recycled water will be delivered to the planned potable reuse facility, VenturaWaterPure.

3.1.2 Consideration of Supplies in Different Hydrologic Conditions

A primary purpose of an UWMP is to identify and quantify water supplies in a normal, single-dry, and multiple-dry years as follows.

- Normal year supply represents the supplies Ventura Water considers available during normal, long-term average conditions.

- The single dry-year supply is the supply anticipated to be available should there be a repeat of past dry conditions. In this UWMP Ventura Water has considered the driest year (for which data is available), by supply source, to estimate the overall single-dry year supply.

- The multiple dry year drought supply considers a five-consecutive-year drought. In this UWMP Ventura Water has evaluated the driest 5-year sequence (for which data is available), by supply source, to estimate supplies in year 1 through year 5 of a drought.

The UWMP Act requires that a supplier compare supplies and demands for these different hydrologic conditions. The UWMP does not try to anticipate specific hydrologic conditions in any particular year, however, the Act does require that a supplier compare supplies and demands assuming a drought extending from year 2021 to 2025. This section of the UWMP goes into details about supplies available in different hydrologic year types, the reader is directed to Section 6 for the comparison of supplies and demands for different hydrologic year types.

3.2 Local Surface Water

3.2.1 Casitas Municipal Water District (Casitas)

Casitas operates and maintains the Ventura River Project, a part of which is the 238,000 AF capacity storage reservoir known as Lake Casitas. Casitas diverts and stores storm water runoff to Lake Casitas for subsequent filtration treatment and supply of potable water to agricultural and urban uses in western Ventura County. The Casitas service area includes the Ojai Valley, the western part of the City, Oak View, Upper Ojai Valley, and the coastal area between the City and Santa Barbara County.

In July 1995, the City signed an operating agreement with Casitas, establishing the City's minimum annual purchase at 6,000 AFY, which was subject to the allocation program described below during drought periods. In May 2017, the City Council and Casitas Board of Directors approved a new Water Services Agreement between the City and Casitas that establishes that Casitas shall supply the City with sufficient water to meet its in-district projected water demand (this agreement is provided as Appendix G). The present five-year (FY 09-10 to FY 13-14) average normal (non-drought) water supply from Casitas is estimated to be 5,062 AFY.

The demand from the proposed development projects that are anticipated to be utilizing water by Fiscal Year 2020 are added to the five-year average normal (non-drought) water supply from Casitas of 5,062 AFY. Projects completed since fiscal year 2014 and projects expected to be completed within calendar year 2020 are assumed to be utilizing water in Fiscal Year 2020. The supply from Casitas is estimated to be 5,425 AFY.

Over the last two years, Casitas has been working to develop its Comprehensive Water Resources Plan and update the yield model for Lake Casitas to incorporate more recent data related to storage capacity, diversion efficiency, hydrology, climate change, and other factors. On April 21, 2021, the Casitas Board of Directors directed staff to reduce the available supply yield for the Casitas System from 20,840 acre-feet per year (AFY) to

15,010 AFY for planning purposes. The Board also directed staff to use a planned demand of 15,525 AFY, which is based on average water production for the Casitas System over the last 10 years (Calendar Year 2011-2020). Based on these actions, Casitas plans to adjust the baseline allocations for its customers and update its Water Event Action Plan (WEAP) ahead of the 2022/2023 Fiscal Year. The City of Ventura will coordinate with Casitas after its WEAP has been updated, to determine if revisions to the 2017 Water Services Agreement are warranted. If adjustments are made to the City's allocation, then this document will be amended at that time.

3.2.1.1 Reliability – Water Quality

Treated surface water from Lake Casitas has historically had levels of disinfection by-products that occasionally exceeded the respective maximum contaminant levels (MCLs) for total trihalomethanes (TTHMs) and haloacetic acids (HAAs). In cases when the levels of TTHMs and HAAs are exceeding or near exceeding the respective MCLs, the City will typically reduce the intake of Casitas water until the issue passes.

Casitas will be implementing potential treatment options to reduce the formation of disinfection by-products in their finished water. In the interim the City will be exploring options at its treatment facility to further reduce the level of disinfection by-products detected in the delivered water.

3.2.1.2 Reliability – Other

No infrastructure issues that may limit planned use of water from Lake Casitas have been identified.

3.2.1.3 Reliability – Water Year Type

The 2017 Water Services Agreement between the City and Casitas indicates that, in the event that Casitas must enact its Water Efficiency and Allocation Program (2015 WEAP) due to a water shortage, Casitas may adjust the City's allocation consistent with the percentage reduction for the WEAP stage.

Casitas has assigned five stages of water storage in Lake Casitas that serve as a guidance to triggering the implementation of water use reduction goals and measures.

Stage Conditions from Casitas Municipal Water District's "Water Efficiency and Allocation Program" dated May 9, 2018

Stage	Stage Title	Lake Casitas Storage (%)	Demand Reduction
1	Water Conservation	100% to 50%	0%
2	Water Shortage Warning	50% to 40%	20%
3	Water Shortage Imminent	40% to 30%	30%
4	Severe Water Shortage	30% to 25%	40%
5	Critical Water Shortage	25% to 0%	50%

As of February 2020, Casitas was in a Stage 3 water supply condition per Casitas Resolution No. 16-00. The lake level as of February 19, 2020 was 41.6 percent full. The Casitas Board of Directors made the decision to remain in a Stage 3 water supply condition in June of 2020.

The Water Services Agreement between Casitas and the City specifies that the City's Stage 1 Allocation shall be the average of the City's Projected Water Demand during the five (5) most recent years during which neither the City nor Casitas are implementing their water shortage contingency plans. The projected water demand from the past five non-drought fiscal years (FY 09-10 to FY 13-14) certification letters from the City to Casitas including demand associated with land use change is 5,425 AFY. A Stage 3 demand reduction of 30% would result in a supply of 3,798 AFY.

Although the Lake is currently slightly above 40% capacity, it is likely that Casitas will remain in a Stage 3 water supply condition. In order to be conservative, this report assumes a reduction of 30% to the City's Casitas supply for the 2021 Supply Drought Impact and a 40% reduction for 2022.

Consistent with the DWR Guidebook, this UWMP evaluates supplies and demands in different hydrologic year types based on past years. For the average year, supply available in 2013 was used; 2014 was selected for the single-dry year; and a repeat of the multi-dry period from 2014-2018 is used to approximate supplies for future long-term droughts. This information is used in coordination with the anticipated WEAP stage and anticipated water demand growth in the portion of the City within Casitas to estimate supply, as reflected in Table 3-1.

TABLE 3-1
ESTIMATED SUPPLY FROM CASITAS MUNICIPAL WATER DISTRICT (AFY)

	2025	2030	2035	2040	2045
Normal Year [1]	5,805	5,963	6,126	6,293	6,465
Single-Dry Year	5,805	5,963	6,126	6,293	6,465
Multi-Year Drought					
Year 1	5,805	5,963	6,126	6,293	6,465
Year 2	4,644	4,771	4,901	5,035	5,172
Year 3	4,064	4,174	4,288	4,405	4,526
Year 4	4,064	4,174	4,288	4,405	4,526
Year 5	4,064	4,174	4,288	4,405	4,526

1 Given the current level of Lake Casitas, Normal supplies may not be available even if average rainfall occurs in a specific year.

3.2.2 Ventura River

Production from the Ventura River is a function of several factors including diversion capacity, local hydrology, environmental impacts, and the storage capacity of the Ventura River alluvium and upstream diversions. Currently all Ventura River water is collected using surface diversion, subsurface collectors, and shallow wells. A surface intake structure at Foster Park is unused due to the natural channeling of the active river system bypassing the structure.

3.2.2.1 Reliability – Water Quality

Surface water from the Ventura River contains natural organics, which results in the formation of disinfection by-products during the treatment and disinfection processes. Turbid water and high levels of organics, such as after heavy rainstorms, can result in treatment issues and high levels of disinfection by-products in the finished water. During these times, which typically occur during rainy months, water from the Ventura River may be significantly reduced until the water quality improves. The City will be implementing potential treatment options to reduce the formation of disinfection by-products in the finished water.

3.2.2.2 Reliability – Other

Production wells at Foster Park were destroyed during 2001 and 2005 storm events. These events have reduced the City's ability to extract water from Foster Park to a maximum capacity of 4,200 AFY. The 2020-2026 Capital Improvement Program includes the Foster Park Wellfield Production Restoration project. The project involves the replacement of the destroyed wells and construction of new facilities to restore historical production capabilities of 6,700 AFY during wet years. Therefore, the projected future water supply from the Ventura River / Foster Park is 4,200 AFY.

3.2.2.3 Reliability – Water Year Type

Due to continued drought conditions and heightened environmental requirements, the City's ability to draw water from the Ventura River continues to be significantly challenged and impacted. The City entered into a settlement with Santa Barbara Channelkeeper in 2019, which was amended in 2020, which requires the City to modify its pumping based on reduced flows in the Ventura River. The current agreement requires the City to turn off the Nye Wells 7 and 8 when the daily average flow rate in the River drops below 4 cubic feet per second (cfs) (for three consecutive days), and to cease operations at the intake facility when flows drop below 3 cfs (for three consecutive days) as measured at the City's stream gauge upstream of Foster Park (VR1). The intake may be shutdown sooner if flows in the River recede quickly.

To evaluate supply into the future, in different year types, historic supply from past years has been evaluated. For the normal year, supply available after 2005 was used; 2015 was selected for the single-dry year; and a repeat of the multi-dry period from 2015-2019 is used to approximate supplies in for future long-term droughts. These supplies have been modified as necessary to reflect assumptions about regulatory and environmental requirements into the future. See Table 3-2.

TABLE 3-2
ESTIMATED SUPPLY FROM VENTURA RIVER (AFY)

	2025	2030	2035	2040	2045
Normal Year	4,200	4,200	4,200	4,200	4,200
Single-Dry Year	1,298	1,298	1,298	1,298	1,298
Multi-Year Drought					
Year 1	1,298	1,298	1,298	1,298	1,298
Year 2	1,298	1,298	1,298	1,298	1,298
Year 3	1,298	1,298	1,298	1,298	1,298
Year 4	1,298	1,298	1,298	1,298	1,298
Year 5	1,298	1,298	1,298	1,298	1,298

3.3 Groundwater

The City obtains water from three groundwater basins, which have historically provided roughly an average of 8,750 AFY (from 2016 to 2020), or 65 percent of the City's total supply. Table 3-3 shows the historical production from these basins. These groundwater basins are described below.

TABLE 3-3
HISTORIC GROUNDWATER PRODUCTION (AFY)

Basin Name	Metered or Unmetered	2016	2017	2018	2019	2020
Mound Basin	Metered	2,671	1,397	2,529	3,286	2,371
Oxnard Plain Basin	Metered	3,702	3,825	3,317	3,323	3,691
Santa Paula Basin	Metered	2,898	2,593	3,096	2,509	2,544
	Total	*9,271*	*7,815*	*8,942*	*9,118*	*8,605*
Groundwater as a % of Total Supply		67%	57%	66%	70%	63%

3.3.1 Mound Groundwater Basin

The Mound Groundwater Basin is identified in DWR Bulletin 118[12], 2003 Update as the Mound Subbasin of the Santa Clara River Valley Groundwater Basin (Basin No. 4-4.03). The basin

[12] Bulletin 118 describes the occurrence and nature of groundwater in California. The publication officially defines groundwater basin boundaries and provides information for each of the State's hydrologic regions. For more information, please see: https://water.ca.gov/Programs/Groundwater-Management/Bulletin-118

underlies the northern part of the Ventura coastal plain and is bounded on the north by the Santa Ynez and Topa Topa Mountains, on the south by the Oak Ridge and Saticoy faults, the northeast by the Santa Paula Subbasin, and the west by the Pacific Ocean.

The Mound Basin is designated high-priority by DWR and the Mound Basin Groundwater Sustainability Agency (MBGSA) has been recognized by DWR as the GSA for the basin. The MBGSA was formed through a Joint Exercise of Powers Agreement (JPA) by and among the United Water Conservation District (UWCD), the City, and the County of Ventura. In addition to representatives from each of the 3 member agencies, the Board of Directors includes an agricultural stakeholder director and environmental stakeholder director. The Mound Basin GSA is required to develop a Groundwater Sustainability Plan that establishes the sustainable yield of the Mound Basin by January 2022.

The Mound Groundwater Basin has historically provided water for overlying beneficial uses and satisfies agricultural, municipal, and industrial demands. Historical use has been documented to temporarily exceed the yield of the basin and result in water levels that have fallen below sea level and created a threat of seawater intrusion. To abate this threat the City abandoned its historical coastal well facilities and located groundwater extraction near the center of the Mound Basin. A report (Fugro 1997) compiled as part of a 1996 study of the basin indicated that historical data supports a basin yield of at least 8,000 AFY during drought conditions as long as pumping is reduced during wet years to allow water levels to recover. The City's average annual extraction from 2000 to 2009 was approximately 4,000 AFY. The remainder of the available yield is utilized by other basin users.

3.3.1.1 Reliability – Water Quality

The Mound Groundwater Basin has elevated total dissolved solids (TDS) and sulfate. Ventura Water blends Mound Basin groundwater with other sources to reduce TDS. While City of San Buenaventura water meets all applicable primary standards, City water does have TDS concentrations that exceed secondary standards (standards set for aesthetic, taste, and odor rather than protection of public health). Water quality is not considered a limitation for using supplies from the Mound Groundwater Basin, but the City continues to look for ways to improve the quality, such as blending with future water supply sources.

3.3.1.2 Reliability – Other

Currently, two City wells withdraw water from the Mound Groundwater Basin: Victoria Well No. 2, which was installed in 1995, and Mound Well No. 1, which began production in April 2003. Pumping from Victoria Well No. 1, which was installed in 1982, was discontinued due to maintenance and water quality issues. The City recently reached an agreement with the County on deeding to the County its interest in Victoria Well No. 1 and leasing land for drilling of Mound Well No. 2. Construction of Mound Well No. 3 is currently in progress and is scheduled to be in production in 2021. Design of Mound Well No. 2 is also in progress and scheduled to be in production in 2022. Mound Well No. 2 will serve as a replacement well for Victoria Well No. 1; Mound Well No. 3 will serve as a backup well.

Due to operational constraints, recent production from the Mound Basin has been lower than the historical 10-year average. Victoria Well No. 2 was not operational in 2020, so the only well producing water from Mound Basin in 2020 was Mound Well No.1. The City's current water supply from the Mound Basin is the current average production rate of Mound Well No. 1 or

2,400 AFY. In the near future, once Mound Wells No. 2 and 3 are operational, production from the Mound Basin will increase.

3.3.1.3 Reliability – Water Year Type

The City finalized a study in March to review the perennial yield of the Mound Basin and determine if the annual average yield of the basin is still believed to be accurate. The Report concludes that the perennial yield of the Mound Basin is between 6,600 and 7,400 AFY. While this is consistent with the long-term average production, it is lower than the average production from 2000-2009 (which is used to determine the City's capacity of 4,000 AFY). The Mound Basin GSA will utilize this analysis in conjunction with other information to determine the Sustainable Yield of the Mound Basin as defined by SGMA. This analysis will not be complete until the Groundwater Sustainability Plan is submitted in 2022.

The groundwater basin is managed over the long-term and variations in year-to-year supply are not anticipated at this time. For this reason, the City's anticipated basin yield, in all hydrologic years, is based on "Fugro West, Inc. June 1997. Mound Groundwater Basin Annual Report" and set at 4,000 AFY.

3.3.2 Oxnard Plain Groundwater Basin

The Oxnard Plain Groundwater Basin is identified in DWR Bulletin 118, 2003 Update as the Oxnard Subbasin of the Santa Clara River Valley Basin (Basin No. 4-4.02), located in southern Ventura County. The basin is bounded on the north by the Oak Ridge fault, the south by the Santa Monica Mountains, the east by the Pleasant Valley and Las Posas Valley Basins, and the west by the Pacific Ocean.

Wells near the Buenaventura Golf Course pump from the Fox Canyon Aquifer of the Oxnard Plain Groundwater Basin. Currently, three wells, Golf Course Wells No. 5, 6, and 7 produce potable water for the City's system. Average annual yield from the City's Golf Course wells over the past 5 years has been about 3,500 AFY.

There are limited carryover provisions provided by the FCGMA in the Oxnard Plain Basin that do allow the City to pump less water in wet years and more water in dry years, but all water must be pumped within five years

3.3.2.1 Reliability – Water Quality

The Oxnard Plain Groundwater Basin has elevated TDS. Ventura Water blends Oxnard Plain Basin groundwater with other sources to reduce TDS. While City of San Buenaventura water meets all applicable primary standards, City water does have TDS concentrations that exceed secondary standards (standards set for aesthetic, taste, and odor rather than protection of public health). Water quality is not considered a limitation for using supplies from the Oxnard Plain Groundwater Basin, but the City continues to look for ways to improve the quality, such as blending with future water supply sources.

3.3.2.2 Reliability – Other

No infrastructure issues that may limit planned use of water from the Oxnard Plain Groundwater Basin have been identified.

3.3.2.3 Reliability – Water Year Type

The Oxnard Plain Groundwater Basin is managed by the Fox Canyon Groundwater Management Agency (FCGMA), which was created by state legislation in an effort to reduce overdraft and stop seawater intrusion. The FCGMA is the Groundwater Sustainability Agency (GSA) for the Oxnard Plain. The Groundwater Sustainability Plan for the Oxnard Subbasin, provided in Appendix H, was completed in December 2019.

At the October 23, 2019 meeting of the FCGMA Board of Directors, there was a unanimous vote to adopt the ordinance for a new pumping allocation system for the Oxnard and Pleasant Valley basins, effective October 1, 2020. The new well-based allocation will be the average pumping for the base period of 2005-2014. On December 12, 2019, the FCGMA Board voted to repeal portions of some past drought ordinances and this set the City's pumping allocation in the Oxnard Plain Basin to 4,827 AFY effective January 1, 2020.

Neither the allocation ordinance nor the GSP establish the pumping reductions that will take place to meet the sustainable yield for the Oxnard Plain Basin. However, the GSP suggests a linear ramp down from current pumping to the estimated sustainable yield by 2040. Based on these estimates, the City can expect (without additional projects being implemented) its allocation to decrease by 44% by 2040. Therefore, the projected future supply for the Oxnard Plain Basin are projected to decline from 5,304 AFY to 2,970 AFY.

3.3.3 Santa Paula Groundwater Basin

The Santa Paula Groundwater Basin is identified in DWR Bulletin 118, 2003 Update as the Santa Paula Subbasin (Basin No.4-4.04). The basin is bounded on the north by the Topa Topa Mountains, the south by the Oak Ridge and South Mountain, the Oak Ridge fault, and the Saticoy fault, the east by a bedrock constriction, and the west by the Oxnard Plain and Mound subbasins. Water from the Santa Paula Basin is extracted through Saticoy Wells No. 2 and No. 3, with a peak pumping capacity of 3,000 GPM.

The management of the Santa Paula Basin was established under a court stipulated judgment entered in 1996 and amended and restated in 2010 (provided in Appendix I). United, the Santa Paula Basin Pumpers Association and the City are all parties to the Judgement. In summary, the Judgment adjudicates groundwater rights, regulates individual and collective pumping, provides for basin management through a Technical Advisory Committee (TAC), and reserves jurisdiction in the Superior Court to resolve future disputes and provide for supplementary orders as necessary. Because the Santa Paula Basin is already managed per a stipulated judgment, it is exempt from most provisions of SGMA.

The Santa Paula Basin Judgment allows the City to utilize 3,000 AFY. The City is not limited to this allocation in any single year but may produce seven times its average annual allocation (21,000 AF) over any running seven-year period. In addition, the City has acquired water rights in the amount of 126 AFY, bringing its current total allocation to 3,126 AFY.

3.3.3.1 Reliability – Water Quality

The Santa Paula Groundwater Basin has elevated TDS and requires treatment for iron and manganese. Water quality is not considered a limitation for using supplies from the Santa Paula

Basin, but the City continues to look for ways to improve the quality, such as blending in the future with SWP water.

3.3.3.2 Reliability – Other

The City currently relies on Saticoy Well No. 3 for production and utilizes Saticoy Well No. 2 as an occasional back-up supply due to decline in production. The estimated annual production capacity for Well No. 3 is 2,450 AFY. The City is planning to construct replacement well Saticoy Well No. 4, which is anticipated to be producing water in 2025.

3.3.3.3 Reliability – Water Year Type

If the monitoring performed by the TAC determines that groundwater safe yield is being exceeded, then the City may have its pumping allocation reduced. Upon and motion and hearing as prescribed in the Judgment, if the Court finds that the safe yield of the Basin is less than the total pumping allocations, the Judgment describes six "Overdraft" stages and requires reduced production at each stage.

- Stage 1: Affects the pumping allocation of the Santa Paula Basin Pumpers Association and not the City.
- Stage 2: City of San Buenaventura pumping limited to 1,141 AFY.
- Stage 3: City of San Buenaventura pumping limited to 641 AFY.
- Stage 4: City of San Buenaventura pumping limited to 481 AFY.
- Stage 5: City of San Buenaventura allocation is reduced to zero.
- Stage 6: Affects the pumping allocation of the Santa Paula Basin Pumpers Association.

If the above Stages were to go into effect, the City's allocation from acquired water rights would be reduced proportionally by the same percentage reduction then required by the members of the Santa Paula Basin Pumpers Association. There is also an exception in the Judgment for emergency conditions for the City to reasonably supply public needs.

Based on recent work completed by the technical working group regarding conditions in the Basin, it is projected that no Stage reductions will be implemented even if the drought remains in effect through 2021. It is also projected that under normal conditions, that the allocation will remain at 3,000 AFY with the addition of water rights equaling 126 AF.

The groundwater basin is managed over-long term and variations in year to year supply are not anticipated. For this reason, anticipated basin yield, in all hydrologic years, is based on the original City allocation plus 126 AFY for City acquired water rights.

3.4 Groundwater Supplies Normal, Single-Dry and Multiple Dry Year

Table 3-4 depicts the anticipated groundwater supplies during Normal, Single-Dry, and Multiple Dry Years, by groundwater source.

TABLE 3-4
PROJECTED GROUNDWATER SUPPLIES FOR DIFFERENT YEAR TYPES (AFY)

	2025	2030	2035	2040	2045
Normal Year					
Mound Basin	4,000	4,000	4,000	4,000	4,000
Oxnard Plain Basin	4,813	4,199	3,584	2,970	2,970
Santa Paula Basin	3,126	3,126	3,126	3,126	3,126
Total Normal Year	*11,939*	*11,325*	*10,710*	*10,096*	*10,096*
Single-Dry Year					
Mound Basin	4,000	4,000	4,000	4,000	4,000
Oxnard Plain Basin	4,813	4,199	3,584	2,970	2,970
Santa Paula Basin	3,126	3,126	3,126	3,126	3,126
Total Single-Dry Year	*11,939*	*11,325*	*10,710*	*10,096*	*10,096*
Multiple-Dry Years					
Mound Basin	4,000	4,000	4,000	4,000	4,000
Oxnard Plain Basin	4,813	4,199	3,584	2,970	2,970
Santa Paula Basin	3,126	3,126	3,126	3,126	3,126
Total Multiple-Dry Year	*11,939*	*11,325*	*10,710*	*10,096*	*10,096*

Note:

In multiple dry years additional groundwater may be utilized to meet demands when surface water supplies are reduced (conjunctive use).

3.5 Recycled Water and Reuse

Recycled water is a current and future source for Ventura Water. Recycled water is detailed in Chapter 4.

3.6 Transfers, Exchanges and Groundwater Banking Programs

Water supplies may be purchased from other water agencies and sources, and the City may explore these opportunities in the future.

As described in Section 3.7.1, the City of San Buenaventura has participated in the SWP turnback pool and exchanged SWP with other State Water Contractors (San Gorgonio Pass Water Agency). Participation in the turnback pool could be considered a transfer.

City does not participate in any official groundwater banking programs. The City has limited ability to bank groundwater. The limited carryover provisions provided by the FCGMA in the Oxnard Plain Basin does allow the City to pump less water in wet years and more water in dry years, but all water must be pumped within five years. In the Santa Paula Basin, the allocation is based on a seven-year running average, so the City can also pump more in dry years and less in wet years as long as the 7-year total is not exceeded in any given 7-year period.

3.7 Planned Water Supply Projects and Programs

Continued new and infill development that is already entitled, along with anticipated future entitlements, will continue to increase overall demand for water in the service area, despite developer contributions to future water supplies through dedication of water rights, implementing extraordinary conservation measures, and/or payment of Water Resource Net Zero fees. Consequently, combined with legal and regulatory requirements on both groundwater and surface water supplies and impacts of climate change, the City has recognized that consumption is nearing available supply and new supply projects need to be implemented. Consistent with Article X, Section 2 of the California Constitution, in order to mitigate the water resource impacts of new or intensified development, it is necessary and desirable for new or intensified development to provide supplemental water resources to the City water system in an amount proportional to the new demand, implement extraordinary conservation measures to offset demand, and/or to pay a water resource fee based upon the cost of obtaining water supplies to meet the demand of new or intensified development. Upon direction from City Council, Ventura Water prepared and evaluated a Water Rights Dedication and Water Resources Net Zero Policy (Net Zero Policy). The Net Zero Policy was developed after months of review and input from the Ventura Water Commission. The City Council adopted the Net Zero Policy in Ordinance 2016-004 and Resolution 2016-027. Revenues from the Net Zero Policy will provide funding for new water supply projects, such as the VenturaWaterPure Program.

Revenues from rates, grants, and loans will finance the following planned supply projects:

- SWP Water
- VenturaWaterPure

Ventura Water has conceptually studied ocean desalination. However, in the Ventura Water Supply Projects Environmental Impact Report (EIR), it was only evaluated at the programmatic level and not the project level of detail. Further evaluation would be required if ocean desalination were pursued as a future supply source.

3.7.1 SWP Water

The City does not physically take SWP Water because it lacks the facilities to do so. However, since at least 1999 has sold, transferred, or exchanged the water to other SWP Contractors. The City has a 10,000 acre-foot per year entitlement from the SWP. The base contractual agreements concerning the City's annual entitlement to 10,000 acre-feet of SWP are: (1) the 1963 State Water Supply Contract of 20,000 acre-feet entitlement of SWP water between the Department of Water Resources (DWR) and Ventura County Watershed Protection District (VCWPD) known formerly as Ventura County Flood Control District (VCFCD); (2) the 1970 agreement between VCFCD and Casitas known formerly as the Ventura Municipal Water District that assigned the 20,000 acre-feet entitlement to Casitas; and (3) the 1971 agreements between Casitas and the City providing the City with an annual entitlement of 10,000 acre-feet and Casitas and United with an annual entitlement of 5,000 acre-feet each.

In the contract with Casitas, the City retains full authority and responsibility for determining the point and method of delivery of the allocation. To date, the City has not constructed the improvements necessary to receive direct delivery of its allocation.

The City pays annual SWP Table A water fees to DWR, which cover construction costs for SWP facilities and administration to deliver allotments of water throughout the state. In addition, the citizens of Ventura participated in an advisory vote on November 3, 1992 and selected desalinating seawater over importing water through the SWP, as the preferred supplemental water supply option. However, based on the City Attorney Office's review of the City's SWP Table A water, the City cannot unilaterally end its involvement in the SWP's financial obligations and SWP Table A water without great risk.

The Monterey Amendment to the State Water Contract in 1999 provided the City a formal mechanism to allow the City to place their SWP water into a “turn back” pool to be purchased by other SWP contractors. The City has taken part in the SWP “turn back” pool over the past several years which has provided a small annual revenue offset. Since 2018, the City has participated in exchanges with San Gorgonio Pass Water Agency which allows the City to receive revenue to offset current SWP fixed costs and receive additional SWP in the future. The City has also worked recently with United who requested to receive the City’s allocation at the “turn back” pool rate which provided water benefits to the County area as a whole.

On January 23, 2017, City Council authorized an alignment study to determine how the interconnection project could be designed and operated to supply water to serve the regional needs of the City, Calleguas, Casitas Municipal Water District, and United Water Conservation District (United). The final alignment study was completed in 2018, and the environmental review process pursuant to CEQA was commenced.

On August 5, 2019, the City of San Buenaventura City Council voted to certify the State Water Interconnection Project Final Environmental Impact Report. As stated in the Final EIR, the project will enable delivery of SWP water by wheeling through Metropolitan Water District of Southern California and Calleguas to the City. The connection will also facilitate direct delivery of SWP water to United and direct or in-lieu delivery of SWP water to Casitas. In addition, the interconnection would allow the City to deliver water to Calleguas during an outage of its imported water supplies and for Calleguas to deliver water to the City during an outage of the City’s water supplies. In both outage scenarios, water delivered would be returned by the receiving party to the providing party following the outage. The interconnection will be a pipeline used to transport water between Calleguas’ and the City’s distribution systems. The pipeline will be approximately 7 miles in length originating in the eastern portion of the City, traversing southerly and easterly through unincorporated Ventura County, to the southwestern end of the City of Camarillo. Final design on the Interconnection began in mid-2020 and construction is anticipated to start the end of 2022.

Benefits to the City include making up for losses in annual yield from existing supply sources (Lake Casitas, Ventura River, and groundwater), improving water quality, and providing a backup supply for the City’s other potential, long-term water supply options. Operational details will be developed through the project design and planning process and negotiations with project partners. These details will be reflected in future CWRRs and UWMPs when available.

While the City’s water supply contract for SWP water provides the City with a maximum annual allocation of 10,000 AF, the actual allocation of available water is set DWR annually. DWR allocations are finalized in the Spring of each year and consider the following:

- hydrologic conditions

- existing storage in reservoirs
- operational and regulatory constraints
- contractor demands

To improve system water quality, Ventura Water anticipates using approximately 1,300 AF of SWP in any year it is available, but this amount may increase to compensate for deficiencies in other supply sources or decrease based on the amount of SWP that might be available.

While the City of San Buenaventura's SWP entitlement (Table A Entitlement) is 10,000 AFY this amount is not the long-term average supply expected. According to Department of Water Resources, Technical Addendum to the State Water Project Final Delivery Capability Report 2019 (August 26, 2020) Table B-32. Ventura County Watershed Protection District Future Conditions:

- The Long-Term Average delivery of SWP to the City of San Buenaventura will be 54% of the Table A Entitlement (5,400 AFY). So, 5,400 AFY is the assumed SWP Normal Year Supply. The City estimates it will need 1,300 AFY to blend with groundwater to improve water quality. Additional water may be used to rest groundwater sources in wet years or if other sources are unavailable.
- The State Water Project Final Delivery Capability Report is based on hydrology from 1922 to 2003 (e.g., the current modeling does not consider years past 2003, including 2015). The single-dry year delivery was in year 1977 and (had the City of San Buenaventura had a means to take the water) delivery would have been 9% of Table A or 900 AFY – this is the Single-Dry Year Supply, according to the 2020 SWP Delivery Capability Report.
- The driest 5-year period would be if years 1930-1934 were replicated.
    - In 1930 about 20% of allocation was available, or about 2,000 AF
    - In 1931 about 33% of allocation was available, or about 3,300 AF
    - In 1932 about 13% of allocation was available, or about 1,300 AF
    - In 1933 about 38% of allocation was available, about 3,800 AF
    - In 1934 about 11% of allocation was available, about 1,100 AF

These amounts may be supplemented based on an agreement with San Gorgonio Pass Water Agency (SGPWA). In 2018 and 2019, the City executed agreements with SGPWA to exchange its State Water Project Allocation. As a result of these agreements, SGPWA is obligated to return 2,075 AF of water to City by 2030 (Ventura Water 2021).

3.7.1.1 Delta Reliance

In the future, a small portion of the water received by Ventura Water may come from the Sacramento-San Joaquin Delta (Delta). The 2020 UWMP Guidebook describes how urban water suppliers that anticipate participating in or receiving water from a "covered action" related to the Delta should provide information in their 2020 UWMPs to demonstrate consistency with *Delta Plan Policy WR P1, Reduce Reliance on the Delta Through Improved Regional Water*

Self-Reliance (Reduced Reliance Policy). DWR has suggested that any entity receiving imported water from the SWP should anticipate being part of a "covered action".

DWR suggests suppliers do the following to demonstrate consistency with WR-P1:

- *Establish a base period for evaluation of Delta water*. Ventura Water has not taken Delta water directly in the past. Rather Ventura Water has paid for participation in the SWP and in some years participated in the "turnback pool" to recoup some costs or sold/exchanged/transferred to others.
- *Provide data on State Water Project Water received in the past*. No SWP water has been received directly in the past.
- *Provide information on supplier contribution to regional self-reliance (local supplies brought online 2010-2045 in 5-year increments)*. Ventura Water has been locally self-reliant for its entire history. To improve local supplies, starting in 2010 Ventura Water developed a recycled water system capable of delivering 700 AFY. Starting in 2025 Ventura Water anticipates producing and utilizing 2,800 AFY advanced treated water (VenturaWaterPure, see section 3.7.2). This has been accompanied with aggressive measures to reduce demand, including public outreach and drought rates. There has been a consistent decline in gallons per capita per day, demonstrating the success of water use efficiency for improving local self-reliance.
- *Project SWP water that will be received by Ventura Water through 2045*. Ventura Water anticipates taking an average of 1,300 AFY SWP starting in year 2025.

Data related to Delta reliance is provided in Appendix J.

3.7.2 VenturaWaterPure

The City of San Buenaventura is currently in the planning phases for the proposed VenturaWaterPure Program which includes additional diversion of tertiary treated effluent discharge from the Santa Clara River Estuary to a new proposed Advanced Water Purification Facility (AWPF) for potable reuse. Potable reuse is the proven use of recycled water to supplement drinking water supplies. After years of special studies, environmental assessment, demonstration facility testing, and stakeholder meetings, the City determined the best way to enhance environmental protection while improving local water quality and supply reliability is to divert highly treated wastewater discharges for potable reuse. The final product of this state-of-the-art AWPF would be a new, locally owned source of highly purified drinking water that provides the City of San Buenaventura with a long-term drought resilient water supply solution. On October 14, 2019, the City of San Buenaventura City Council unanimously voted to certify the EIR for the Ventura Water Supply Projects, which included a project level environmental review of the VenturaWaterPure Program. The City is currently working on the next steps on this Program including land acquisition, permitting, final design, and bidding for construction.

Based on the completion of the Special Studies and additional assessments detailed in the Final EIR, the future water supply provided by the VenturaWaterPure Program is projected to be at least 2,800 AFY in Phase 1a and 4,000 AFY in Phase 1b.

3.7.3 Ocean Desalination

In 2013, City staff was engaged in discussions with local water agencies in regard to potential regional desalination projects. In the City's 2015 UWMP, seawater desalination was included as a potential future part of the City's long term water supply portfolio and as an additional emergency water supply during times of drought. The desalination facility would be designed with a delivery capacity of up to 2.7 million gallons per day or 3,000 AFY.

According to the Ventura Water Supply Projects EIR certified on October 14, 2019, if sufficient water supply is not available from the VenturaWaterPure Program, then the City may need to develop desalination facilities to meet future water supply needs. Phase 2 of the proposed projects would augment water supplies to meet future water needs, including the accommodation of planned growth, either through increasing the amount of recycled water produced, or construction of an ocean desalination facility. This would be accomplished through either the expansion of the AWPF as a first option pending regulatory approvals, or, if this option is not approved or does not meet the City's water supply needs, through construction of an ocean desalination facility. Since ocean desalination was only evaluated at a program level in the Ventura Water Supply Projects EIR and environmental impacts were not evaluated in detail, ocean desalination is not quantified as a potential additional future supply source.

3.8 Anticipated Water Supply Sources in Normal, Single Dry, and Multiple Dry Years

Table 3-5 shows Ventura Water supplies in 2020. Tables 3-6, 3-7, and 3-8 provide details on supplies anticipated to be available to Ventura Water in average/normal, single-dry, and multiple dry years given existing and planned supplies.

TABLE 3-5
WATER PRODUCTION CALENDAR YEAR 2020 (AF)

Water Supply Source	Volume (AF)	Type
Casitas Municipal Water District [a]	2,533	Drinking Water
Ventura River [b]	2,417	Drinking Water
Groundwater [c]	8,606	Drinking Water
Recycled Water [d]	564	Recycled Water
Total Supplies	**14,120**

e See Section 3.7. Because other supplies are likely to be reduced in multi-year drought use of SWP water is assumed.

f See Section 3.7.

g Maximum supplies do not account for reduction to meet water quality objectives.

3.9 Energy Intensity of the City of San Buenaventura's Water System

Water energy intensity is the amount of energy, calculated on a whole-system basis, required for use of water in a specific location, such as the Ventura Water service area. DWR provides guidance for calculating the operational energy intensity of water, defined as the total amount of energy expended by the urban water supplier on a per AF basis to take water from the location where the urban water supplier acquires the water to its point of delivery. DWR requires that urban water suppliers only report the energy intensity associated with water management processes occurring within their operational control and not include energy embedded in water supplies purchased from a wholesale water agency. Table 3-9 below provides an estimate, using the total utility approach, of the water energy intensity of Ventura Water's potable water system. DWR's Energy Intensity spreadsheet is provided in Appendix K.

Table 3-9
Energy Intensity Ventura Water Potable Water Supply -Total Utility Approach

Start Date for Reporting 10/1/2017	**Sum of All Water Management Processes**	**Non-Consequential Hydropower**	
End Date for Reporting 9/30/2018	*Total Utility*	*Hydropower*	*Net Utility*
Volume of Water Entering Process (AF)	13850.54	0	13850.54
Energy Consumed (kWh)	10,042,668	0	10,042,668
Energy Intensity (kWh/MG)	2225.2	0	2225.2

Section 4: Recycled Water and Reuse

This section of the Plan describes the existing and future recycled water opportunities available to the City service area. The description includes estimates of potential supply and demand for 2020 to 2045 in five-year increments, as well as the City's incentives and optimization plan.

4.1 Recycled Water Planning

The City has access to recycled water supply through the Ventura Water Reclamation Facility (VWRF). The City has sole ownership in the wastewater treatment and water recycling facilities in its service area. Currently, the VWRF discharges most of its tertiary treated effluent to the Santa Clara River Estuary with approximately 576 AFY diverted as recycled water for landscape irrigation.

The City has been planning a potable reuse facility to increase their recycled water supply. The City began planning for the VenturaWaterPure facility in 2015 and has since nearly completed the planning phase. As such, the City is not planning to expand their recycled water system beyond this but will continue to deliver the recycled water that they have historically delivered from the VWRF.

4.1.1 Wastewater Collection and Treatment

The VWRF is permitted at 14 million gallons per day (MGD) and discharges up to 9 MGD. The VWRF currently discharges an average of 6.6 MGD. The VWRF provides wastewater collection and treatment service for approximately 98 percent of City residences as well as McGrath State Beach Park and the North Coast Communities (County Service Area No 29). In February 2016, the City took over sewer service for the formerly unincorporated Montalvo community served by Montalvo Community Services District. The VWRF produces recycled water that is treated to tertiary Title 22 standards through tertiary filtration and disinfection. Currently, approximately 6 percent of the treated effluent is reused as recycled water; the rest is discharged to the SCRE.

The City's wastewater collection system consists of approximately 290 miles of sewer pipelines ranging in size from 4 to 42 inches, 11 wastewater lift stations, and the VWRF, a tertiary treatment plant. In addition, the City has recently taken over the 7.5 miles of sewer mains formerly owned by the Montalvo Community Services District. The collection system conveys flows generally from east to west and north to south, culminating at the VWRF for treatment.

The City first provided a municipal sewer system more than a century ago. In 1888, this system extended from Crimea Street west to the Ventura River and from the Pacific Ocean north to Ramona Street. The City later built and operated a primary treatment facility that included an ocean outfall at the foot of Figueroa Street between 1929 and 1959. At that time the outfall was abandoned, and the treatment plant replaced with a pump station, which delivered all wastewater flow from the western portion of Ventura through a 3-mile force main to the VWRF. The VWRF, at 1400 Spinnaker Drive, was constructed in 1958 as a 4 MGD secondary treatment facility utilizing trickling filters. The facility is located on the north bank of, and discharges treated effluent to the SCRE. The facility has provided reclaimed water since the

1970's to the City owned Olivas Park Municipal Golf Course approximately one-quarter mile east of the treatment plant. In 1972 the facility was expanded with the addition of a 10 MGD Activated Sludge treatment process. At that time tertiary filters were also constructed to provide filtered effluent for both reclamation and discharge to the SCRE. Subsequent facility construction projects have added solids treatment, nutrient removal, improved chloramine contact and expanded reclamation pumping and distribution facilities.

Table 4-1 documents wastewater collection in 2020; Table 4-2 documents wastewater treatment and discharge in 2020.

TABLE 4-1
WASTEWATER COLLECTED WITHIN SERVICE AREA 2020 (AF)

Name of Wastewater Collection Agency	Wastewater Volume Metered or Estimated?	Volume of Wastewater Collected in 2020	Name of Agency Receiving Collected Wastewater	Treatment Plant Name	Is WWTP Located Within UWMP Area?	Is WWTP Operation Contracted to a Third Party?
City of San Buenaventura	Metered	8,108	City of San Buenaventura	Ventura Water Reclamation Facility	Yes	No

Note: Currently, approximately 6% of the treated effluent is reused as recycled water, the remaining is discharged to the Santa Clara River Estuary.

TABLE 4-2
WASTEWATER TREATED AND DISCHARGED WITHIN SERVICE AREA 2020

Wastewater Treatment Plant Name	Discharge Location/ Method of Disposal	Does the Plant Treat Wastewater Generated Outside the Service Area?	Treatment Level
Ventura Water Reclamation Facility	Discharge to Santa Clara River Estuary	No	Tertiary

Wastewater Treated (AF)	Discharged Treated Wastewater (AF)	Recycled Within Service Area (AF)	Recycled Outside of Service Area (AF)
8,108	7,544	564	0

Current Recycled Water Uses

Recycled water from the VWRF is used for general irrigation of two public golf courses, a City park and nearby landscape areas. After the VenturaWaterPure facility is constructed and

operational, the City still plans to provide recycled water from the VWRF for the same irrigation purposes. Existing recycled water uses include:

- Golf courses - Olivas Links Golf Course and Buenaventura Golf Course irrigation
- Parks - Marina Park irrigation
- Others - Landscape irrigation near Olivas Drive and in the Harbor area.

The two golf course customers, Olivas Links Golf Course and the Buenaventura Golf Course, account for approximately 90 percent of the total recycled water. In addition, discharge to the Estuary is also considered a beneficial use of the recycled water. Table 4-3 provides a summary of existing actual recycled water uses compared to the projected values in the 2015 UWMP.

In 2016, in response to the drought, the City increased its efforts to replace potable demand with recycled water demand. The City implemented a program, referred to as the mobile reuse program, whereby commercial and industrial entities and City residents can use a recycled water filling station at the VWRF. The filing station is used by multiple entities such as AERA Energy, the Ventura County Transportation Department, the City of San Buenaventura City Parks Department, and the San Buenaventura State Park, in addition to City residents, for the self-hauling of recycled water for irrigation and dust control. The mobile reuse program was in operation through part of 2020, however, was paused due to the COVID-19 pandemic.

TABLE 4-3
2015 UWMP RECYCLED WATER USE PROJECTION
COMPARED TO 2020 ACTUAL (AF)

Surface Water Augmentation	0	0
Direct Potable Reuse	0	0
Other	0	0
Total	**700**	**564**

4.1.2 Potential and Projected Use

Recycled water could be put to potable reuse at the VenturaWaterPure facility. In 2015, the City initiated a pilot project to test the feasibility of constructing an advanced water purification facility (AWPF) to maximize quantity and reliability of potable supplies by purifying tertiary treated effluent produced by the VWRF and optimizing its potable reuse, rather than discharging into the SCRE. The pilot facility operated for 9 months and produced favorable results, indicating highly reliable purification technologies, providing information on operational needs and costs, and the absence of risk to public health and safety. As a result, the City is proceeding with the design of a full-scale AWPF.

Other Methods to Expand Recycled Water Use

The City will expand their recycled water use significantly via the VenturaWaterPure facility and is not planning to further expand traditional recycled water use.

Projected Recycled Water Demand

Table 4-4 shows the projected recycled water uses including the historic uses for golf course, park, and landscape irrigation (excluding the VenturaWaterPure facility).

TABLE 4-4
PROJECTED RECYCLED WATER USES

Beneficial Use Type	2025	2030	2035	2040	2045

Notes:

a VenturaWaterPure accounted for in Tables 3-6 through 3-8.

4.1.3 Methods to Encourage Recycled Water Use

Ventura Water is focusing efforts on potable reuse through the VenturaWaterPure facility but will encourage customers to continue to participate in the mobile reuse program and will require new construction projects to utilize recycled water for landscape irrigation if located adjacent to a recycled water pipeline.

Section 5: Water Quality

The quality of any natural water is dynamic in nature. This is true for surface water and local groundwater. During periods of intense rainfall or snowmelt, routes of surface water movement are changed; new constituents are mobilized and enter the water while other constituents are diluted or eliminated. The quality of water changes over the course of a year. These same basic principles apply to groundwater. Depending on water depth, groundwater will pass through different layers of rock and sediment and leach different materials from those strata. Water depth is a function of local rainfall and snowmelt. During periods of drought, the mineral content of groundwater increases. Water quality is not a static feature of water, and these dynamic variables must be recognized.

The City's water sources are within current and anticipated Environmental Protection Agency (EPA) and State Water Resources Control Board Division of Drinking Water (DDW) levels for primary water quality standards. Based on current conditions and knowledge, water quality is not anticipated to affect water supply reliability. However, water quality issues are constantly evolving. It is well recognized water quality treatment can have significant costs.

The City's east side receives its water from groundwater wells and has significantly higher levels of TDS and minerals (hardness) compared to the water delivered to the City of San Buenaventura's west end. As such, TDS levels in excess of 1,000 parts per million (ppm) are experienced on a daily basis in the eastern portions of the system. To meet secondary water quality standards, the DDW encourages the City to explore ways to limit TDS levels to 1,000 ppm. At this time, groundwater from multiple wells in both the Mound and Oxnard Plain basins are treated and blended at the Bailey Treatment Plant to achieve the lowest TDS levels possible without sacrificing supplies. Groundwater in the Mound Basin is high in TDS and sulfate. Some portions of the groundwater exceed the sulfate maximum contaminant level (MCL) of 500 ppm, with conditions between 421 and 790 ppm in the distribution system (Ventura Water 2020). To improve TDS water quality additional westside water supplies or treatment of eastside sources will be required (Ventura Water 2020). The initial target is to lower TDS levels in the eastern portion of the system to 1,000 ppm by 2025 with possible further reduction in the future. The City continues to monitor for regulated as well as unregulated contaminants, in the event they are added to the contaminants list in future drinking water standards.

The City is also planning a blending strategy to improve groundwater quality. Some of the City's SWP allocation would help mitigate water quality issues via blending at the Saticoy Conditioning Facility. Water from the VenturaWaterPure facility would also be used to blend water at the Bailey Treatment Plant.

Section 6: Reliability Planning

6.1 Overview

The Act requires urban water suppliers to assess water supply reliability that compares total projected water use with the expected water supply over the planning period in five-year increments. The Act also requires an assessment for a single dry year and a multiple year drought lasting 5 years. This chapter presents the reliability assessment for the Ventura Water service area.

6.2 Normal Water Year

The normal/average year is a year in the historical sequence that most closely represents median runoff levels and patterns. This section summarizes Ventura Water supplies available to meet demands over the 25-year planning period during an average/normal year and compares them to demands for the same period. Assumptions about supplies and demands are provided in Chapters 2 and 3. Table 6-1 demonstrates that with planned supplies (see section 3.7) the City anticipates adequate supplies for years 2025 to 2045 under Normal conditions.

TABLE 6-1

Difference as % of Demand	***61%***	***72%***	***73%***	***65%***	***62%***

Notes:

a See Table 3-6

b Maximum supplies do not account for potential reductions to meet water quality objectives.

During the Water Commission Meeting on October 27, 2015 the Water Commission determined that it was appropriate to use a supply surplus buffer of 20% for normal hydrological years. The buffer has been used for the purpose of determining water supply needs and capital cost estimates for building or attaining new supply sources that will meet the surplus buffer. Table 6-1 demonstrates that, per Water Commission policy and as a result of the water supply planning conducted over the last 5 years, City water supplies after 2025 will be adequate.

6.2.1 Single-Dry Year

The water supplies and demands for the Ventura Water service area over the 25-year planning period were analyzed in the event that a single-dry year occurs. Table 6-2 summarizes the existing and planned supplies available to meet demands during an assumed single-dry year. Table 6-2 anticipates that with the planned supplies coming online after 2025, supplies will be sufficient to meet demands in a single-dry year.

TABLE 6-2
COMPARISON OF SUPPLIES AND DEMANDS IN SINGLE-DRY YEAR (AF)

	2025	2030	2035	2040	2045
Supplies					
Casitas Municipal Water District [a]	5,805	5,963	6,126	6,293	6,465

Notes:

a See Table 3-7

b Maximum supplies do not account for potential reductions to meet water quality objectives.

6.2.2 Multiple-Dry Year

The water supplies and demands for Ventura Water's service area over the 25-year planning period were analyzed in the event that a five-year multiple-dry year event occurs. Table 6-3 summarizes the existing and planned supplies available to meet demands during multiple-dry years. Table 6-3 documents that with planned supplies, Ventura Water should be able to meet demands in a multiple-dry year period.

TABLE 6-3
COMPARISON OF SUPPLIES AND DEMANDS IN MULTIPLE-DRY YEARS (AF)

	2025	2030	2035	2040	2045
Supplies [a, b]					
Year 1	21,618	23,962	24,710	24,263	24,435

Notes:

a See Table 3-8

b Maximum supplies do not account for potential reductions to meet water quality objectives.

6.2.3 Summary of Comparisons

As shown in the analyses above, with planned supplies, Ventura Water has adequate supplies to meet demands during average, single-dry, and multiple-dry years.

6.3 Drought Risk Assessment

The Water Code requires that every urban water supplier include in its UWMP, a drought risk assessment for its water service to its customers. This is to benefit and inform the demand management measures and water supply projects and programs to be included in the urban water management plan.

Annually Ventura Water prepares a CWRR. This report will form the basis for the Annual Assessment of shortage (see Appendix L). As part of preparing the CWRR, Ventura Water looks in detail at anticipated supplies and demands for the current year and two future years and also provides longer term projections.

6.3.1 Data and Methodologies Used

6.3.1.1 Water Demands

The water demands for this UWMP utilize water demand factors developed in April 2020, used in the 2021 CWRR. These water demand factors have been applied to the existing and anticipated land uses in the Ventura Water service area. The water demand factors looked at billing data for the City, for various uses, for the period 2013 through 2018, a water loss factor was applied to the raw factor, and a planning-level contingency factor was applied to account for variability due to weather and drought. The water demand factors capture changes in demand due to water conservation and codes and standards that have occurred overtime. Because growth in the Ventura Water service area is minimal (approximately 0.54% a year) it is not necessary to apply a different water demand factor to new dwellings. The current water demand factors are used and have been adjusted to account for new dwellings. Applying an optimistically “low” water demand factor on new development could skew demand trends when it is uncertain if (a) the development will truly occur and (b) the development will have a truly low water demand.

To evaluate water demand, Ventura Water has examined current and projected land uses. The land use evaluation started with the current general plan and a summary of built dwelling-units (residential) and square footage (non-residential). Using known development projects constructed since the adoption of the general plan, a summarized total of the existing land use within the City service area through the end of the recent calendar year was developed.

The City of San Buenaventura maintains a database of projects that are in the City’s planning process and categorizes the projects as: “In Planning Process,” “In Plan Check,” “Under Construction,” or have “All Planning Approvals.” Ventura Water has evaluated the database for projects that are either “Under Construction,” or have “All Planning Approvals.” In coordination with City Planning, Ventura Water has created a table of the “Under Construction and Approved Projects” anticipated to utilize water in the near term, which is defined as the next five years.

Using the anticipated land uses and the water demand factors Ventura Water has estimated water demands 2021 through 2025 shown in Table 6-11 below.

6.3.1.2 Water Supplies

This Drought Risk Assessment looks at all the water supplies anticipated to be available 2021 through 2025, including any limitations due to infrastructure, regulations, and assuming drought conditions.

Casitas Municipal Water District

As of February 2020, Casitas is currently in a Stage 3 water supply condition per Casitas Resolution No. 16-00. The current lake level as of February 19, 2020 was 41.6 percent full. The Casitas Board of Directors made the final decision to remain in a Stage 3 water supply condition in June of 2020. The City's calendar year 2020 supply from Casitas was 3,794 AF.

Although the Lake is currently slightly above 40% capacity, it is likely that Casitas will remain in a Stage 3 water supply condition. To be conservative, a reduction of 30% to the City's Casitas supply for 2021 and a 40% reduction for 2022, and a 30% reduction 2023 to 2025 are assumed. However, due to growth in the Casitas service area, there is a slight increase in the amount of water the City is eligible to receive from Lake Casitas. This growth is also accounted for in the anticipated drought supplies shown in Table 6-4.

TABLE 6-4
ANTICIPATED SUPPLIES FROM CASITAS CONSECUTIVE DRY YEARS 2021-2025 (AF)

2021	2022	2023	2024	2025
3,798	3,864	3,369	2,864	2,185

Notes:

Assumes 30% reduction in supply Years 2021, 2023, 2024, and 2025
Assumes 40% reduction in supply Year 2022

Ventura River

Production from the Ventura River is limited by infrastructure, the settlement with Santa Barbara Channelkeeper, and low-flow hydrology as detailed in section 3.2.2 and summarized in Table 6-5 below.

TABLE 6-5
ANTICIPATED SUPPLIES FROM VENTURA RIVER
CONSECUTIVE DRY YEARS 2021-2025 (AF)

2021	2022	2023	2024	2025
736	1,298	1,298	1,298	1,298

Notes:

Assumes repeat of the average two driest years (2015-2016) for year 2021

Assumes repeat of single-driest year (2015) for years 2022-2025

Groundwater

As described in Sections 3.3 and 3.4, groundwater supplies are anticipated to be reliable sources of supply for the City. Table 6-6 reflects the anticipated supplies. In Table 6-6 a gradual turn-down of supply from the Oxnard Plain subbasin is assumed to account for pumping reductions anticipated as part of implementation of the GSP.

TABLE 6-6
ANTICIPATED GROUNDWATER SUPPLIES
CONSECUTIVE DRY YEARS 2021-2025 (AF)

	2021	2022	2023	2024	2025
Mound	3,270	4,000	4,000	4,000	4,000
Oxnard Plain	5,304	5,181	5,058	4,936	4,813
Santa Paula Basin	2,661	2,661	2,661	2,661	3,126
Total	*11,235*	*11,842*	*11,719*	*11,597*	*11,939*

State Water Project

SWP water is not anticipated to be available in the Ventura Water service area until 2025. For the purposes of the Drought Risk Assessment, it is assumed the SWP is also experiencing a 5-year drought and supply is assumed to be similar to year 1935 hydrology (State Water Project Final Delivery Capability Report 2019 (August 26, 2020) Table B-32), see Table 6-7.

TABLE 6-7
ANTICIPATED SWP SUPPLIES
CONSECUTIVE DRY YEARS 2021-2025 (AF)

2021	2022	2023	2024	2025
-	-	-	-	1,100

Notes:
No delivery infrastructure until 2025. Assumes year 1934 hydrology based on State Water Project Final Delivery Capability Report 2019 (August 26, 2020) Table B-32

VenturaWaterPure

The VenturaWaterPure Project is planned to be operable in 2025, but may not be producing regular supply until after 2025. Therefore, Table 6-8 does not include supply from VenturaWaterPure. For subsequent years, supply from VenturaWaterPure is estimated to be 2,800 AFY after 2025 and 4,000 AF after year 2030, in all hydrologic year types.

TABLE 6-8

Notes:

1. The gross water use value assumes the worst-case scenario of less than 50% of normal rainfall and applies a 10% upward adjustment to the demand projections.

Section 7: Demand Management Measures

7.1 Demand Management

The purpose of the Demand Management Measures (DMM) section of this UWMP is to (a) provide a description of the past water conservation programs that Ventura Water has implemented since 2016 to meet its urban water use reduction targets and (b) describe the activities and actions Ventura Water plans to use in the future to meet its urban water use reduction targets. For the purposes of this UWMP the DMMs are categorized as "Foundational" and "Other". Foundational DMMs, listed below, are those DMMs that the UWMP Act and Water Code specifically mention:

a. Water waste prevention ordinances
b. Metering
c. Conservation pricing
d. Public education and outreach
e. Programs to assess and manage distribution system real loss
f. Water conservation program coordination and staffing support

Activities outside of the Foundational DMMs that encourage less water use in the City service area fall in the "Other DMM" category.

This chapter discusses the DMMs that Ventura Water undertakes as part of normal business. However, given the extraordinary and continuing drought, this chapter also describes those measures that were undertaken specifically to address dry conditions.

7.1.1 Foundational DMMs

7.1.1.1 Water Waste Prohibition

Ventura Water prohibits water waste through its Water Conservation Ordinance (Division 22 – Public Utilities, Chapter 22.170). Specifically, Section 22.170.010 states:

"Water waste prohibited.

A. Prohibited uses. No person shall use or permit the use of water:
    1. For the watering of turf, ornamental landscape, open ground crops and trees, including agricultural irrigation, in a manner or to an extent which allows water to run to waste;
    2. Such that the escape of water through leaks, breaks or malfunction within the water user's plumbing or distribution system occurs for any period of time beyond which such break or leak should reasonably have been discovered and corrected. It shall be presumed that a period of 48 hours after the water user discovers such leak, break or malfunction, or receives notice from the city of such

condition, whichever occurs first, is a reasonable time within which to correct such condition;

3. In conjunction with use of a handheld hose to wash automobiles, trucks, trailers, boats, or other types of mobile equipment without the use of a workable positive shutoff nozzle;
4. For the operation of any ornamental fountain, or similar structures, unless water for such use is recycled for lawful reuse without substantial loss;
5. For washing of sidewalks, walkways, driveways, parking lots or any other hard-surfaced areas by hose or flooding, except as otherwise necessary to prevent or eliminate conditions dangerous to the public health and safety or for other legitimate necessity;
6. For serving of water by a restaurant to its customers without first being requested by the customer;
7. The application of potable water to outdoor landscaped during and within 48 hours of measurable rainfall; or
8. Knowingly for any indiscriminate running of water or washing with water not otherwise prohibited above which is wasteful and without reasonable purpose."

7.1.1.2 Metering

All existing services and new service connections in the City are metered and billed volumetrically

Efforts in 2020

In March 2016, the City Council adopted the Meter Upgrade Project to replace all manually-read water meters with advanced metering infrastructure (AMI) that automatically relay water usage to the City's billing system through a secured network. The project launched in October 2018, with plans to replace all 32,000 Ventura Water meters by October 2021. To date, the project is 75 percent complete with over 25,000 meters installed.

In April 2020, Ventura Water launched Home Connect, a new online portal that allows Ventura Water customers to track their hourly water usage, set water-use budgets, and receive leak detection notifications for improved water use management. Upon completion, the Meter Upgrade Project is projected to save more than 600 acre-feet of water per year.

7.1.1.3 Conservation Pricing

All of the City's retail customers are metered and billed with commodity rates for both water and sewer service. The City does not have any unmetered services and all new connections are metered and billed volumetrically.

Efforts in 2020

Every five years, a Cost of Service and Rate Design Study is conducted for the water and wastewater enterprises to ensure fair and equitable rates for all City customers and to generate sufficient revenue to meet operating and capital costs. In response to seasonal drought conditions, the City has periodically adopted and implemented new rate structures. These

events occurred in Fiscal Year (FY) 2012-2013, FY 2014-2015, and FY 2015-2016, in response to water shortage events. New rates were established to achieve full revenue recovery during drought and non-drought years. In May 2020, the City declared a Stage 2 Water Shortage Event, shifting from the Stage 3 Water Shortage Event declared in September 2015 that remained in effect through June 30, 2020. The City is currently conducting a new Water and Wastewater Rate Design Study. If adopted by City Council, new rates will be implemented in July 2021.

7.1.1.4 Public Education and Outreach

Ventura Water has consistently and actively encouraged water conservation through an extensive public education and outreach campaign. Outreach has utilized multiple venues including social media, printed media (bill inserts, handouts), outdoor advertising (billboards), radio, television, hosting of water conservation workshops, participation in community events (parades and street fairs). These outreach activities are summarized in Table 7-1.

TABLE 7-1
VENTURA WATER OUTREACH PROGRAMS

Action	Description	2016	2017	2018	2019	2020
Monthly E-Newsletter	The monthly Pipeline Newsletter provides information on capital improvement projects, conservation programs, public meetings, workshops, and special events.	X	X	X	X	X
Website	Ventura Water regularly updates the website with FAQs, public notices, water quality data, water conservation information, public meeting information, project updates, and more.	X	X	X	X	X
Outreach Events	15-20 public outreach events per year, consisting of job fairs, City-sponsored events, Chamber of Commerce events, with giveaways and informational handouts.	X	X	X	X	X
Social Media	Ventura Water maintains an active and engaged presence on Facebook, Twitter, YouTube, and Instagram.	X	X	X	X	X
Public Engagement Materials	Water quality Consumer Confidence Report. Brochures “Protecting our Pipes”; “Understanding Water and Wastewater Charges”; “Customer Assistance Program”; “Water Disaster Preparedness”; and “Fats, Oils, and Grease”.	X	X	X	X	X
Targeted Outreach	Brochures, annual mailer, postcards, and door hangers.	X	X	X	X	X
Conservation Giveaways	Ventura Water continues to offer customers water conservation giveaways including materials such as “Doing Our Part to Save Water” yard signs, low-flow showerheads, faucet aerators, toilet leak detection kits, shower times, dish squeegees, and more.	X	X	X	X	X

Table 7-1 cont.

Action	Description	2016	2017	2018	2019	2020
WaterWise Gardening Series	Ventura Water, in partnership with the city's Environmental Sustainability Department, offers monthly workshops that cover water wise and sustainable gardening practices.	X	X	X	X	X
Townhall Meetings/ Public Informational Meetings	Ventura Water plans, attends, and hosts public meetings to share water shortage rates information, ordinance changes, and customer programs to provide an opportunity for residents to voice concerns	X	X	X	X	X
Customer Water Waste Hotline	Hotline where customers can report water waste.	X	X	X	X	X
Water Take 1	A home grown international short film contest that brings awareness to the value of water.	X	X	X	X	X

Between September 2016 and July 2018, Ventura Water held nine water conservation contests to bring awareness of saving water during drought periods to the community.

The Ventura Water Outreach team, an assembly of Ventura Water staff who represent the laboratory, the wastewater collections system, the wastewater plant operations, water distribution, and the General Managers office host and attend multiple events to perform face to face public engagement related to drought messaging (see Table 7-2).

7.1.1.5 Programs to Assess and Manage Distribution System Real Loss

Consistent with Senate Bill 555, Ventura Water conducts a water loss audit each year and provides a report to DWR. For the January to December 2019 period, Ventura Water utilized the Water Audit Methodology (Appendix L of the Guidebook) to estimate both real and apparent water loss. Based on this recent audit, the City estimates that apparent losses (meter inaccuracies) account for about one percent of total water loss; real losses are estimated to be about 7 percent of production. The Water Loss Audit Reports for 2015-2019 are provided in Appendix E.

7.1.1.6 Water Conservation Program Coordination and Staffing Support

The conservation program is managed by Ventura Water's Management Analyst, who oversees water resources management for the City. Program activities are managed by various City staff as part of their regular assignment, which equates to one full time employee.

TABLE 7-2
DROUGHT SPECIFIC OUTREACH PROGRAMS

Monthly class March – October 2016 - 2019	Water Wise Gardening Class
March 2016 - 2018	Wild and Scenic Film Festival
March 2016 - 2019	Water Take 1 Event
April 2016 - 2019	AWA Water Symposium
April 2016 - 2019	Earth Day Ecofest
March 2017 – December 2018	Channel Islands Native Garden Plant Sale
April 2017	Pierpont Elementary Earth Day Event
April 2017	E.P. Foster Earth Day Event
May 2016 - 2018	Surf N Suds
July 2017	Smart Sprinkler Controller Workshop
April 2018	Walk for Water
May 2018	Ocean Friendly Garden/Water Conservation Workshop
May 2019	Water Wise Workshop with WCDC
August 2019	Summer Open House Event at Ventura Water Reclamation Facility

7.1.2 Other DMMs

7.1.2.1 Wholesale Agency Assistance Programs

Ventura Water will continue to work cooperatively with Casitas Municipal Water District to participate in regional DMM programs, informational groups and projects, determination of the most cost-effective DMMs, and tailoring programs specific to the City. Ventura Water customers that are within the Casitas service area qualify for many conservation incentives, including water audits, free low flow showerheads and aerators, and rebates for high efficiency toilets and washing machines. These conservation opportunities are described at Casitas' website (www.casitaswater.org). Water conservation activities undertaken by Casitas in the Ventura Water area are summarized in Table 7-3.

An example of coordination between Ventura Water and Casitas is the Water Wise Incentive Program. The Water Wise Incentive Program is a new regional water conservation program that provides outdoor water use efficiency incentives to customers of Ventura Water, the City of Santa Paula and Casitas Municipal Water District. Starting in 2016, the Water Wise Incentive Program began offering rebates for turf removal, weather-based irrigation controllers, high-efficiency nozzles, and rainwater harvesting and reuse. The City, Casitas, and the City of Santa Paula cooperatively designed the program and successfully pursued grant funding for the project.

TABLE 7-3
VENTURA WATER PARTICIPATION IN WHOLESALE AGENCY PROGRAMS

Description	2016	2017	2018	2019	2020
Water Efficiency Surveys	72	81	116	94	98
High Efficiency Toilets (1.1 gpf)	-	-	-	21	33
High Efficiency Washing Machine Rebates	29	56	14	53	106
Weather-Based Irrigation Controllers	14	134	130	113	82
High Efficiency Sprinkler Nozzles	873	1,629	4,465	2,578	1,205
Instant Hot Water Recirculating Pump	-	-	-	227	241
Rain Barrel Voucher	295	122	92	109	62

To date, Ventura Water's Water-Wise program has resulted in an estimated water savings of 104 AFY.

7.1.2.2 Ventura Water Partnerships with Ventura Unified School District

Since 2009, the City of San Buenaventura Water Department and Environmental Sustainability Division have provided environmental educational programming to Ventura Unified School District in the form of classroom presentations, assemblies, special event participation, special projects and equipment (i.e. recycle bins, composting bins, gardening supplies). Over 30,000 students have received education on water conservation, stormwater pollution prevention and waste reduction.

In 2017, Ventura Water provided financial support and technical staff support to Juanamaria Elementary School and ATLAS Elementary schools for projects and programs that increase recycling, build wildlife habitats, and reduce waste and water consumption.

In 2017, Ventura Water provided financial support and technical staff support to Ventura High School Greener World Action Team for replacing 1,100 square feet of turf with a water wise landscape at Ventura High School.

In 2018, Ventura Water provided financial support and technical staff support to ATLAS Elementary School for implementing a water wise garden on campus.

Green School Program

Ventura Water offers free education classroom presentations to students in Kindergarten through 12th grade. Lesson plans are grade-specific and aligned with Next Generation Science Standards. All lesson plans included hands-on activities, covering topics such as water conservation, water resource management, watershed protection, and more. This program aims to bring awareness of the importance of local water resource management and water conservation as a way of life.

Table 7-4 summarizes the school outreach metrics.

TABLE 7-4

	2016	2017	2018	2019	2020
# of students	-	6,210	5,800	4,150	*
# of presentations	-	240	234	125	-

*Postponed due to COVID-19.

Field Trips

Beginning in 2016, Ventura Water partnered with MERITO Foundation, a local-based nonprofit organization dedicated to providing meaningful watershed experiences to multicultural youth and their community. Students, parents, and educators were invited to visit the Ventura Water Reclamation Facility for a day of hands-on science-based learning. Students tour the Ventura Water Reclamation Facility, conduct water quality testing out of Ventura Water's on-site wildlife ponds and assess ecosystem health through bird species identification. Through this field experience, students are exposed to careers in water science and the many roles and responsibilities necessary to sustain a safe and healthy environment. Ventura Water offers free field trips to the reclamation and drinking water treatment plants throughout the school year. Teachers and educators can schedule a field trip on Ventura Water's website. Since 2016, Ventura Water has provided field trips for over 1,600 students.

7.1.2.3 Efforts In 2020

WaterWise Turf and Replacement Program

Since 2015, the City has offered $2 per square foot rebates to qualifying customers that replace their lawn with a water wise landscape. To date, approximately 633 projects have been completed with more than 520,000 square feet of turf removed, resulting in a project water savings of 21 AFY. This program continues to be offered to Ventura Water customers.

Mobile Reuse Program

In June 2016, the City launched a Residential Mobile Reuse Program which provides high-quality recycled water for local residents and commercial businesses. The recycled water can be picked up at the Fill Station located at the Ventura Water Reclamation Facility. Residents, City Parks, and State Parks utilize the water for landscape irrigation while AERA Energy and the Ventura County Transportation Department utilize the water for dust control mitigation. Benefits of the program include expanded recycled water usage in the City and conservation of potable water. To date, the Residential Mobile Reuse Program has provided over 51 acre-feet in recycled water.

Enforcement of Water Waste Prohibition

Ventura Water staff continues to monitor and respond to water waste incidents. Residents are encouraged to anonymously report water waste through a website form or by calling Ventura Water Customer Care. City staff investigates an average of 10 water waste incidents per month.

7.2 Planned DMMs to Meet Water Use Targets

Ventura Water customers have already achieved demand reductions sufficient to meet SBX7-7 water use targets. Ventura Water will continue to perform Foundational DMMs. These DMMs, expanding opportunities for new recycled water use customers in the service area, as well as potable reuse, will help the City to keep its GPCD within or lower than the SBX7-7 water use targets.

Section 8: Water Shortage Event Contingency Plan

Ventura Water has prepared a separate standalone Water Shortage Event Contingency Plan (WSECP), contained in Appendix L. The WSECP was adopted by the City Council on April 26th, 2021. This section includes a brief summary of the WSECP and includes the drought risk assessment required by the UWMP Guidelines.

8.1 Purpose of the WSECP

The City of San Buenaventura has developed a WSECP to provide guidance if triggering events occur — whether from reduced supply, increased demand, or an emergency declaration — and to identify corresponding actions to be taken during the various stages of a water shortage. The plan includes voluntary and mandatory stages which are intended to be fair to all water customers and users while having the least impact on business, employment, and quality of life for residents.

8.2 Annual Assessment

New provisions in Water Code Section 10632.1. require that an urban water supplier such as Ventura Water, conduct an annual water supply and demand assessment ("Annual Assessment"), on or before July 1 of each year, to be submitted to DWR. As part of the WSECP Ventura Water has identified the timeline, staff and outside agency coordination, and other actions necessary to conduct the Annual Assessment.

8.3 Shortage Stages

The WSECP describes six water shortage stages corresponding to progressive ranges of up to 10, 20, 30, 40, and 50 percent shortages and greater than 50 percent shortage.

8.4 Water Shortage Response Actions

The WSECP identifies water shortage response actions, including:

- Communication with customers
- Public outreach
- Supply augmentation
- Operational changes
- Customer demand reduction measures (including enforcement)
- Monitoring of production and demand

State of California
Office of Administrative Law

In re: **State Water Resources Control Board**	**NOTICE OF APPROVAL OF REGULATORY ACTION**
Regulatory Action:	**Government Code Section 11353**
Title 23, California Code of Regulations	**OAL File No. 2013-0422-02 S**
Adopt sections: 3939.45 **Amend sections:** **Repeal sections:**	

This Government Code section 11353 rulemaking by the State Water Resources Control Board (Board) amends the Water Quality Control Plan for the Los Angeles Region as adopted by the Los Angeles Regional Water Resources Control Board (Regional Board) on December 6, 2012, pursuant to Resolution No. R12-011 and approved by the Board on February 19, 2013, pursuant to Resolution No. 2013-0005. These basin plan amendments establish a Total Maximum Daily Load (TMDL) for algae, nutrients, and eutrophic conditions in the Ventura River including the river's estuary and tributaries. The TMDL established in this action allows for an implementation schedule of six to twelve years depending on the source.

OAL approves this regulatory action pursuant to section 11353 of the Government Code.

CONCISE SUMMARY OF REGULATORY PROVISIONS

TITLE 23. Waters
Division 4. Regional Water Quality Control Boards
Chapter 1. Water Quality Control Plans, Policies, and Guidelines
Article 4. Los Angeles Region

§ 3939.XX - "A Total Maximum Daily Load for Algae, Nutrients, and Eutrophic Conditions in the Ventura River including the Estuary and its Tributaries".

On December 6, 2012, the Los Angeles Regional Water Quality Control Board adopted Resolution No. R12-011, amending the Water Quality Control Plan for the Los Angeles Region (Basin Plan) by establishing a Total Maximum Daily Load (TMDL) for Algae, Nutrients, and Eutrophic Conditions in the Ventura River including the Estuary and its Tributaries. The TMDL includes numeric targets for dissolved oxygen and pH equal to their numeric water quality objectives in the Basin Plan. The TMDL also includes numeric targets for algal and phytoplankton biomass and percent cover as numeric interpretations of the water quality condition that will demonstrate attainment of the narrative water quality objective for biostimulatory substances in the Basin Plan. The method to develop these numeric targets is based on the California Nutrient Numeric Endpoints (NNE) approach, developed by U.S. EPA Region 9 and the State and Regional Water Quality Control Boards. The TMDL includes waste load allocations (WLAs) and load allocations (LAs) for discharges from the Ojai Valley Waste Water Treatment Plant (WWTP), the Ventura County Municipal Separate Storm Sewer (MS4), the Caltrans MS4, agriculture sources, horse/intensive livestock activities, grazing activities, general industrial and construction stormwater permittees, onsite wastewater treatment systems, and other National Pollution Discharge Elimination System (NPDES) permittees in the Ventura River watershed in order to attain numeric targets.

The regulatory mechanisms used to implement the WLAs include the Ojai Valley WWTP NPDES permit, the Ventura County MS4 permit, the Caltrans MS4 permit, the general industrial storm water permits, the general construction storm water permits, and other NPDES permits. The regulatory mechanisms used to implement the LAs include Basin Plan discharge prohibitions, waste discharge requirements (WDRs), and waivers of WDRs or other regulatory mechanisms in accordance with the State Nonpoint Source Implementation and Enforcement Policy (NPS Policy). The TMDL allows for an implementation schedule of up to 6-12 years to meet the WLAs and LAs, depending on the source. Discharge monitoring to demonstrate compliance with WLAs and LAs shall be included in the regulatory mechanisms for each source, and ambient monitoring to assess watershed-wide waterbody conditions shall be conducted either individually or cooperatively among all dischargers.

STATE WATER RESOURCES CONTROL BOARD
RESOLUTION NO. 2013-0005

APPROVING AN AMENDMENT TO THE WATER QUALITY CONTROL PLAN FOR THE LOS ANGELES REGION TO INCORPORATE A TOTAL MAXIMUM DAILY LOAD FOR ALGAE, EUTROPHIC CONDITIONS, AND NUTRIENTS IN THE VENTURA RIVER, INCLUDING THE ESTUARY, AND ITS TRIBUTARIES

WHEREAS:

1. On December 6, 2012, the Regional Water Quality Control Board for the Los Angeles Region (Los Angeles Water Board) adopted Resolution No. R12-011, an amendment to the Water Quality Control Plan for the Los Angeles Region (Basin Plan amendment), to incorporate a Total Maximum Daily Load (TMDL) for algae, eutrophic conditions, and nutrients in the Ventura River, including the Estuary, and its tributaries.

2. The Los Angeles Water Board found that the analysis contained in the California Environmental Quality Act (CEQA) "Substitute Environmental Documents" for the proposed Basin Plan amendment, including the CEQA Checklist, the final staff report entitled "Algae, Eutrophic conditions, and Nutrients Total Maximum Daily Loads for Ventura River and its Tributaries," and the responses to comments complies with the State Water Board's regulations for the implementation of CEQA, as set forth in the California Code of Regulations, Title 23, sections 3775 through 3781. The State Water Board has reviewed the Substitute Environmental Documents for the Basin Plan amendment and concurs with the Los Angeles Water Board's findings and determinations, including the Statement of Overriding Considerations.

3. The Los Angeles Water Board also adopted the Basin Plan amendment pursuant to the "Necessity" standard of the Administrative Procedures Act, Government Code section 11353, subdivision (b).

4. The Los Angeles Water Board found the Basin Plan amendment is consistent with the Statement of Policy with Respect to Maintaining High Quality of Waters in California (State Water Board Resolution No. 68-16) and the federal Antidegradation Policy (40 C.F.R. § 131.12), in that it does not allow degradation of water quality, but requires restoration of water quality and attainment of water quality standards during dry weather and maintenance of existing water quality and attainment of water quality standards in wet weather.

5. The State Water Board finds that the Basin Plan amendment is in conformance with Water Code section 13240, which specifies that regional water quality control boards may revise basin plans, and section 13242, which requires a program of implementation for achieving water quality objectives, and section 13141, which requires an estimate of the total cost of the implementation of an agricultural water quality control program, along with an identification of potential sources of financing. The State Water Board also finds that the TMDL as reflected in the Basin Plan amendment is consistent with the requirements of section 303(d) of the federal Clean Water Act.

6. A Basin Plan amendment does not become effective until approved by the State Water Board and until the regulatory provisions are approved by the Office of Administrative Law (OAL). The TMDL must also receive approval from the U.S. Environmental Protection Agency (U.S. EPA).

7. Los Angeles Water Board staff determined that minor, non-substantive changes to the language of the Basin Plan amendment were necessary to correct minor clerical errors or to improve clarity and consistency. The Los Angeles Water Board's Executive Officer made these minor non-substantive changes in a memorandum dated January 8, 2013. The memorandum contains correcting language to the Implementation Plan section of the Basin Plan amendment in order to be consistent with the total phosphorus load and waste load allocations and to accurately reflect the intention of the Los Angeles Water Board.

THEREFORE BE IT RESOLVED THAT:

The State Water Board:

1. Approves the Basin Plan amendment adopted under Los Angeles Water Board Resolution No. R12-011.

2. Authorizes and directs the Executive Director or designee to submit the Basin Plan amendment adopted under Los Angeles Water Board Resolution No. R12-011 to OAL for approval of the regulatory provisions and to U.S. EPA for approval of the TMDL.

CERTIFICATION

The undersigned Clerk to the Board does hereby certify that the foregoing is a full, true, and correct copy of a resolution duly and regularly adopted at a meeting of the State Water Resources Control Board held on February 19, 2013.

ABSENT:	Board Member Steven Moore
ABSTAIN:	None

Jeanine Townsend
Clerk to the Board

State of California
California Regional Water Quality Control Board, Los Angeles Region

RESOLUTION NO. R12-011
December 6, 2012

Amendment to the Water Quality Control Plan for the Los Angeles Region to Incorporate a Total Maximum Daily Load for Algae, Eutrophic Conditions, and Nutrients in Ventura River, including the Estuary, and its Tributaries

WHEREAS, the California Regional Water Quality Control Board, Los Angeles Region (Regional Board) finds that:

1. The Federal Clean Water Act (CWA) requires the Regional Board to establish water quality standards for each waterbody within its region. Water quality standards include beneficial uses, water quality objectives that are established at levels sufficient to protect those beneficial uses, and an antidegradation policy to prevent degrading waters. Waterbodies that do not meet water quality standards are considered impaired.

2. Section 303(d)(1) of the CWA requires each state to identify the waters within its boundaries that do not meet water quality standards. Those waters are placed on the state's "303(d) List" or "Impaired Waters List". For each listed water, the state is required to establish the Total Maximum Daily Load (TMDL) of each pollutant impairing the water quality standards in that waterbody. Both the identification of impaired waters and TMDLs established for those waters must be submitted to the United States Environmental Protection Agency (U.S. EPA) for approval pursuant to CWA section 303(d)(2).

3. A consent decree between U.S. EPA, Heal the Bay, and Santa Monica BayKeeper was approved on March 22, 1999, which resolved litigation between those parties relating to the pace of TMDL development in the Los Angeles Region. The consent decree directs the U.S. EPA to ensure that TMDLs for all 1998-listed impaired waters in the Los Angeles Region be established within 13 years of the consent decree. The consent decree combined waterbody pollutant combinations in the Los Angeles Region into 92 TMDL analytical units. In accordance with the consent decree, the Algae, Eutrophic Conditions, and Nutrients TMDL for Ventura River (including the Estuary and its Tributaries) addresses the listing for algae, eutrophic conditions, nitrogen, and low dissolved oxygen in Ventura River Estuary, Ventura River Reaches 1 and 2, San Antonio Creek and Cañada Larga (Analytical Unit 88). In 2010, the consent decree was modified to include an extension for Analytical Unit 88 until March 2013. Based on the consent decree schedule, TMDLs addressing these listings must be approved or established by U.S. EPA by March 2013.

4. The elements of a TMDL are described in sections 130.2 and 130.7 of Title 40 of the Code of Federal Regulation (40 CFR) and section 303(d)(1), subdivisions (C) and (D), of the CWA, as well as in U.S. EPA guidance documents (Report No. EPA/440/4-91/001). A TMDL is defined as the sum of the individual waste load allocations for point sources, load allocations for non-point sources, and natural background. (40 CFR § 130.2.) TMDLs must be set at levels necessary to attain and maintain the applicable narrative and numeric water quality standards with seasonal variations and a margin of safety that takes into account any lack of knowledge concerning the relationship between effluent limitations and water quality. (40 CFR § 130.7(c)(1).) Section 130.7 of Title 40 of the Code of Federal Regulations also dictates that TMDLs shall take into account critical conditions for stream flow, loading, and water quality parameters. TMDLs typically include one or more numeric "targets"; i.e., numerical translations of the existing water quality standards that represent attainment of those standards, contemplating the TMDL elements described above. Since a TMDL must represent the "total" load, TMDLs must account for all sources of the relevant pollutants, irrespective of whether the pollutant is discharged to impaired or unimpaired upstream reaches.

5. Neither TMDLs nor their targets or other components are water quality objectives, and thus their establishment does not implicate California Water Code section 13241. Rather, under California law, TMDLs are programs to implement existing standards (including objectives), and are thus established pursuant to California Water Code section 13242. Moreover, TMDLs do not create new bases for direct enforcement against dischargers apart from the existing water quality standards they translate. Like most other parts of the Water Quality Control Plan for the Los Angeles Region (Basin Plan), TMDLs are not generally self-implementing. The targets merely establish the bases through which load allocations (LAs) and waste load allocations (WLAs) are calculated. The LAs and WLAs may be implemented in any manner consistent with the Water Quality Control Policy for Addressing Impaired Waters: Regulatory Structure and Options, adopted by the State Water Resources Control Board (State Board) on June 16, 2005 (Resolution No. 2005-0050). Federal regulations also require that National Pollutant Discharge Elimination System (NPDES) permits be consistent with the assumptions and requirements of available WLAs. (40 CFR § 122.44(d)(vii)(B).)

6. As envisioned by California Water Code section 13242, the TMDL contains a "description of surveillance to be undertaken to determine compliance with objectives." The Compliance Monitoring element of the TMDL recognizes that monitoring will be necessary to assess the progress of pollutant load reductions and improvements in water quality in the Ventura River Watershed. The TMDL establishes the types of data and information that will be necessary to obtain. The Regional Board's Executive Officer will ensure that appropriate entities develop and submit monitoring programs and technical reports necessary to achieve the purposes of the TMDL. The Executive Officer will determine the scope of these

programs and reports, taking into account any legal requirements, including this TMDL, and if necessary issue appropriate orders to appropriate entities.

7. Upon establishment of TMDLs by the State or U.S. EPA, the State is required to incorporate, or reference, the TMDLs into the State Water Quality Management Plan. (40 CFR §§ 130.6(c)(1), 130.7.) The Basin Plan and applicable statewide plans serve as the State Water Quality Management Plans governing the watersheds under the jurisdiction of the Los Angeles Regional Board. Attachment A to this resolution contains the language to be incorporated into the Basin Plan for this TMDL.

8. The Ventura River watershed is located in the northwestern portion of Ventura County with a small portion in the southeastern portion of Santa Barbara County. The watershed is characterized by rugged mountains in the upper basins transitioning to less steep areas and valleys. The watershed drains an area of about 220 square miles with an elevation ranging from 6,000 feet to sea level. Major tributaries to the river, include Matilija Creek, North Fork Matilija Creek, San Antonio Creek, Coyote Creek, and Cañada Larga. The river starts at the confluence of Matilija Creek and North Fork Matilija Creek and flows for about 16 miles in a southern direction to the estuary and Pacific Ocean. The river has intermittent direct discharges to the ocean; longshore transport of sand can cause a sand bar to form at the mouth of the estuary in the late summer and early fall obstructing flow.

9. In addition to natural variations in flow, flow regimes in the Ventura River have been altered to support water supply. Lake Casitas and Matilija Reservoir are the two reservoirs within the watershed. Perennial flow occurs from the headwaters to the Robles Diversion Dam, located about two miles downstream from the Matilija Dam. The flow downstream of the Robles Diversion Dam to the confluence with San Antonio Creek is intermittent, particularly during the dry summer months. Flow in the river is disrupted at Foster Park due to subsurface diversions and groundwater extraction. However, the river flow below Foster Park to the estuary increases due to effluent discharges from the Ojai Valley Wastewater Treatment Plant.

10. Eighty-five percent of the land use in the Ventura River watershed is classified as open space and with approximately half of the watershed located within the Los Padres National Forest. Approximately 4.5 percent of the watershed consists of agricultural land with the developed area being small compared to the open space and agriculture. The cities of Ojai and Ventura are the largest urban areas in the watershed and the communities of Casitas Springs, Foster Park, Oak View, Valley Vista, Mira Monte, Meiners Oaks, Upper Ojai, and Live Oak Acres are within the unincorporated Ventura County.

11. The Regional Board's goal in establishing the TMDL for algae, eutrophic conditions, and nutrients in the Ventura River Watershed is to protect the water

contact recreation (REC-1) and non-contact water recreation (REC-2) beneficial uses, as well as uses associated with habitat preservation and protection as applicable including: warm fresh water habitat (WARM), cold fresh water habitat (COLD), estuarine habitat (EST), wetland habitat (WET), marine habitat (MAR), wildlife habitat (WILD), rare, threatened, or endarngered species (RARE), migration of aquatic organisms (MIGR), and spawning, reproduction, and/or early development (SPWN).

12. Regional Board staff have prepared a detailed technical document that analyzes and describes the specific necessity and rationale for the development of this TMDL. The technical document entitled "Algae, Eutrophic Conditions, and Nutrients Total Maximum Daily Loads for Ventura River and its Tributaries" is an integral part of this Regional Board action and was reviewed, considered, and accepted by the Regional Board before acting. Further, the technical document provides the detailed factual basis and analysis supporting the problem statement, numeric targets (interpretation of the narrative and numeric water quality objectives used to calculate the waste load and load allocations), source analysis, linkage analysis, waste load allocations (for point sources), load allocations (for non-point sources), margin of safety, and seasonal variations and critical conditions of this TMDL.

13. On December 6, 2012, prior to the Regional Board's action on this resolution, a public hearing was conducted on this TMDL. Notice of the hearing was published in accordance with the requirements of California Water Code section 13244. This notice was published in the Ventura County Star on July 20, 2012.

14. The public has had a reasonable opportunity to participate in the review of this TMDL. A draft of the TMDL was released for public comment on July 20, 2012; a Notice of Hearing was published and circulated 45 days preceding Regional Board action. The draft of the TMDL was also made available on the Regional Board's website. Regional Board staff responded to oral and written comments received from the public; and the Regional Board held a public hearing on December 6, 2012 to consider adoption of the TMDL.

15. In amending the Basin Plan to establish this TMDL, the Regional Board considered the requirements set forth in sections 13240 and 13242 of the California Water Code.

16. Because the TMDL implements existing narrative and numeric water quality objectives (i.e., water quality objectives in the Basin Plan), the Regional Board (along with the State Board) has determined that adopting a TMDL does not require the Regional Board to consider the factors of California Water Code section 13241. The consideration of the California Water Code section 13241 factors, by section 13241's express terms, only applies "in establishing water quality objectives." Here, the Regional Board is not establishing water quality objectives, but as required by section 303(d)(1)(C) of the Clean Water Act is

adopting a TMDL that will implement the previously established objectives that have not been achieved. In making this determination, the Regional Board has considered and relied upon a legal memorandum from the Office of Chief Counsel to the State Board's basin planning staff detailing why TMDLs cannot be considered water quality objectives. (See Memorandum from Staff Counsel Michael J. Levy, Office of Chief Counsel, to Ken Harris and Paul Lillebo, Division of Water Quality: *The Distinction Between a TMDL's Numeric Targets and Water Quality Standards*, dated June 12, 2002.)

17. While the Regional Board is not required to consider the factors of California Water Code section 13241, it nonetheless has developed and received significant information pertaining to the California Water Code section 13241 factors and has considered that information in developing and adopting this TMDL. Section 13241, at a minimum, requires that water quality objectives ensure reasonable protection of beneficial uses. The designated beneficial uses in the Ventura River Watershed include aquatic life habitat uses, water contact recreation, and non-water contact recreation, navigation, ground water recharge, agricultural supply, municipal and domestic supply, and industrial service supply. The estuary has the designated use of navigation, commericial and sport fishing, and shellfish harvesting. In addition upstream reaches along with the listed tributaries are also designated for industrial service supply. The past, present and probable future beneficial uses of water have been considered in that the Ventura River Watershed is designated for a number of beneficial uses in the Basin Plan.

18. The environmental characteristics of the watershed are spelled out at length in the Basin Plan and in the technical documents supporting this Basin Plan amendment, and have been considered in developing this TMDL. Water quality conditions that reasonably could be achieved through the coordinated control of all factors that affect water quality in the area have been considered. This TMDL provides several compliance options, including improved nitrification-dentrification at the WWTP, structural best management practices (BMPs) such as constructed wetlands, biofiltration, agricultural BMPs and source reduction BMPs, as well as non-structural BMPs and alternatives such as pollution prevention, inspection and proper servicing of onsite waste treatment systems, and outreach and education. These options provide flexibility for responsible parties to reduce nutrient loading to the river, its tributaries, and the estuary. Attainment of the water quality standards through the compliance options is a reasonably achievable water quality condition for the watershed. However, to the extent that there would be any conflict between the consideration of the factor in California Water Code section 13241(c), if the consideration were required, and the Clean Water Act, the Clean Water Act would prevail.

19. Economic considerations were considered throughout the development of the TMDL. Some of these economic considerations arise in the context of Public Resources Code section 21159 and are equally applicable here. The implementation program for this TMDL recognizes the economic limitations on

achieving immediate compliance and allows a flexible implementation schedule of 6 to 12 years to meet the load and waste load allocations, depending on the source. The need for housing within the region has been considered, but this TMDL is unlikely to affect housing needs. Whatever housing impacts could materialize are ameliorated by the flexible nature of this TMDL and the 6- to 12-year implementation schedule.

20. The amendment is consistent with the State Antidegradation Policy (State Board Resolution No. 68-16), and the federal Antidegradation Policy (40 CFR § 131.12), in that it does not allow degradation of water quality, but requires restoration of water quality and attainment of water quality standards.

21. Pursuant to Public Resources Code section 21080.5, the Resources Agency has approved the Regional Boards' basin planning process as a "certified regulatory program" that adequately satisfies the California Environmental Quality Act (CEQA) (Public Resources Code, § 21000 *et seq.*) requirements for preparing environmental documents. (14 Cal. Code Regs. § 15251(g); 23 Cal. Code Regs. § 3782). The Regional Board staff has prepared "substitute environmental documents" for this project that contain the required environmental documentation under the State Board's CEQA regulations. (23 Cal. Code Regs. § 3775-3781.) The project itself is the establishment of a TMDL for algae, eutrophic conditions, and nutrients in the Ventura River Watershed. While the Regional Board has no discretion to not establish a TMDL (the TMDL is required by federal law), the Board does exercise discretion in assigning waste load allocations and load allocations, determining the program of implementation, and setting various milestones in achieving the water quality standards. The CEQA checklist and other portions of the substitute environmental documents contain significant analysis and numerous findings related to impacts and mitigation measures.

22. A CEQA Scoping meeting was conducted on May 30, 2012 at the Ventura City Hall Community Meeting Room to solicit input from the public and interested stakeholders in determining the appropriate scope, content, and implementation options of the proposed TMDL. At the meeting, staff presented the regulatory background, description of the project, location of the project, project purpose, and potential implementation alternatives. Staff received input from members of the regulated community, the Ventura River Watershed Council, the environmental community, and other stakeholders regarding reasonably foreseeable methods of compliance, reasonably foreseeable environmental impacts of the methods of compliance, reasonably foreseeable mitigation measures, reasonably foreseeable alternative means of compliance, and alternatives to the project. This meeting fulfilled the requirements under CEQA. (Public Resources Code § 21083.9; 23 Cal. Code Regs. § 3775.5). A notice of the CEQA Scoping meeting was sent to interested parties on May 16, 2012.

23. In preparing the substitute environmental documents, the Regional Board has considered the requirements of Public Resources Code section 21159 and section 15187 of Title 14 of the California Code of Regulations, and intends those documents to serve as a tier 1 environmental review. This analysis is not intended to be an exhaustive analysis of every conceivable impact, but an analysis of the reasonably foreseeable consequences of the adoption of this regulation, from a programmatic perspective. The "Lead" agencies for tier 2 projects will assure compliance with project-level CEQA analysis of this programmatic project. Project level impacts will need to be considered in any subsequent environmental analysis performed by other public agencies, pursuant to Public Resources Code section 21159.2.

24. The reasonably foreseeable methods of compliance for this TMDL include improved nitrification-denitrification at the WWTP; structural BMPs including constructed wetlands, alum injection systems, and biofiltration systems; agricultural BMPs including filter strips, improved irrigation efficiency, manure management, and grazing management; an anaerobic biodigester; onsite wastewater treatment system upgrades; and watershed-wide implementation, including riparian buffer strips and stream bank stabilization. Foreseeable methods of compliance also include non-structural BMPs, such as onsite wastewater treatment system inspections and servicing, manure management plans, illicit discharge ordinances and preventation plans, and outreach and education.

25. Consistent with the Regional Board's substantive obligations under CEQA, the substitute environmental documents do not engage in speculation or conjecture. The substitute environmental docuemnts only consider the reasonably foreseeable environmental impacts, including those relating to the reasonably foreseeable methods of compliance, reasonably foreseeable feasible mitigation measures to reduce those impacts, and the reasonably foreseeable alternative means of compliance, which would avoid or reduce the identified impacts.

26. The proposed Basin Plan amendment could have a potentially significant adverse effect on the environment. However, there are feasible alternatives, feasible mitigation measures, or both, that if employed, would substantially lessen the potentially significant adverse impacts identified in the substitute environmental documents. Such alternatives or mitigation measures are within the responsibility and jurisdiction of other public agencies, and not the Regional Board. California Water Code section 13360 precludes the Regional Board from specifying the design, location, type of construction, or particular manner in which responsible parties comply with Regional Board orders. When the parties responsible for implementing this TMDL determine how they will proceed, the parties responsible for those parts of the project can and should incorporate such alternatives and mitigation into any subsequent projects or project approvals. These feasible alternatives and mitigation measures are described in more detail

elsewhere in the substitute environmental documents. (14 Cal. Code Regs. § 15091(a)(2).)

27. The substitute environmental documents for this TMDL, and in particular the Environmental Checklist and staff's responses to comments, identify broad mitigation approaches that should be considered at the project level.

28. To the extent significant adverse environmental effects could occur, the Regional Board has balanced the economic, legal, social, technological, and other benefits of the TMDL against the unavoidable environmental risks and finds that specific economic, legal, social, technological, and other benefits of the TMDL outweigh the unavoidable adverse environmental effects, such that those effects are considered acceptable. The basis for this finding is set forth in the substitute environmental documents. (14 Cal. Code Regs. § 15093.)

29. The regulatory action meets the "Necessity" standard of the Administrative Procedures Act. (Gov. Code, section 11353(b).) As specified above, federal law and regulations require that TMDLs be incorporated, or referenced, in the state's water quality management plan. The Regional Board's Basin Plan is the Regional Board's component of the water quality management plan, and the Basin Plan is how the Regional Board takes quasi-legislative planning actions. Moreover, the TMDL is a program of implementation for existing water quality objectives and is, therefore, appropriately a component of the Basin Plan under Water Code section 13242. The necessity of developing a TMDL is established in the TMDL staff report, the section 303(d) list, and the data contained in the administrative record documenting the algae, eutrophic conditions, nitrogen, and low dissolved oxygen impairments in the Ventura River Watershed.

30. The Basin Plan amendment incorporating a TMDL and implementation schedule for algae, eutrophic conditions, and nutrients in the Ventura River Watershed must be submitted for review and approval by the State Board, the State Office of Administrative Law (OAL), and pursuant to CWA section 303(d) and/or 303(c) (as appropriate) by the U.S. EPA. The Basin Plan amendment will become effective upon approval by U.S. EPA. Once effective, a Notice of Decision will be filed with the Resources Agency.

31. If during the State Board's approval process, Regional Board staff, the State Board or State Board staff, or OAL determine that minor, non-substantive modifications to the language of the amendment are needed for clarity or consistency, the Executive Officer should make such changes consistent with the Regional Board's intent in adopting this TMDL, and should inform the Regional Board of any such changes.

32. Considering the record as a whole, this Basin Plan amendment is expected to result in an effect, either individually or cumulatively, on wildlife resources.

THEREFORE, be it resolved that pursuant to sections 13240 and 13242 of the California Water Code, the Regional Board hereby amends the Basin Plan as follows:

1. The Regional Board hereby approves and adopts the CEQA substitute environmental documentation, which was prepared in accordance with Public Resources Code section 21159 and section 15187 of Title 14 of the California Code of Regulations, and directs the Executive Officer to sign the environmental checklist.

2. Pursuant to sections 13240 and 13242 of the California Water Code, the Regional Board, after considering the entire record including oral testimony at the hearing, hereby adopts the amendments to Chapter 7 of the Water Quality Control Plan for the Los Angeles Region, as set forth in Attachment A hereto, to incorporate the elements and implementation schedule of the Algae, Eutrophic Conditions, and Nutrients Total Maximum Daily Loads for Ventura River, including the Estuary, and its Tributaries.

3. The Executive Officer is directed to forward copies of the Basin Plan amendment to the State Board in accordance with the requirements of section 13245 of the California Water Code.

4. The Regional Board requests that the State Board approve the Basin Plan amendment in accordance with the requirements of sections 13245 and 13246 of the California Water Code and forward it to the OAL for review and approval and finally, for review and approval pursuant to CWA sections 303(d) and/or 303(c), as appropriate, to the U.S. EPA.

5. If during the State Board's approval process, Regional Board staff, the State Board or State Board staff, or OAL determine that minor, non-substantive modifications to the language of the amendment are needed for clarity or consistency, the Executive Officer is authorized to make such changes, and shall inform the Regional Board of any such changes.

6. The Executive Officer is authorized to request a "No Effect Determination" from the Department of Fish and Game, and/or transmit payment of the applicable fee as may be required to the Department of Fish and Game.

I, Samuel Unger, Executive Officer, do hereby certify that the foregoing is a full, true, and correct copy of a resolution adopted by the California Regional Water Quality Control Board, Los Angeles Region, on Decmber 6, 2012.

7-35 Ventura River and Tributaries Algae, Eutrophic Conditions, and Nutrients TMDL
7-35.1. Ventura River and Tributaries Algae, Eutrophic Conditions, and Nutrients TMDL - Elements
7-35.2. Ventura River and Tributaries Algae, Eutrophic Conditions, and Nutrients TMDL - Implementation Schedule

Chapter 7. Total Maximum Daily Loads (TMDLs) Summaries
Add:
7-35 Ventura River and Tributaries Algae, Eutrophic Conditions, and Nutrients TMDL

This TMDL was adopted by:

The Regional Water Quality Control Board on December 6, 2012**.**

This TMDL was approved by:

The State Water Resources Control Board on **[Insert date].**
The Office of Administrative Law on **[Insert date].**
The U.S. Environmental Protection Agency on **[Insert date].**

This TMDL is effective on **[Insert Date].**

The elements of the TMDL are presented in Table 7-35.1 and the Implementation Plan in Table 7-35.2.

Table 7-35.1. Ventura River and Tributaries Algae, Eutrophic Conditions, and Nutrients TMDL: Elements

TMDL Element	Regulatory Provisions
Problem Statement	The Ventura River Estuary and Reaches 1 and 2 are on the Clean Water Act (CWA) section 303(d) list as impaired for algae and eutrophic conditions. San Antonio Creek and Cañada Larga are on the CWA section 303(d) list as impaired for nitrogen and dissolved oxygen, respectively. Recent data confirm these impairments and demonstrate additional impairments for low dissolved oxygen in the Estuary, San Antonio Creek, and Reaches 1-4. The algae and nutrient-related impairments are caused by excessive loading of nutrients, particularly nitrogen and phosphorus, to Ventura River and its tributaries. The water quality impairments due to eutrophication and increased nutrient loading occur during the dry season when algae growth primarily occurs. For purposes related to this TMDL, the dry season is defined as occurring from May 1 to September 30. The water quality objectives used to assess impairment for this TMDL are the narrative water quality objective for biostimulatory substances and the numeric water quality objectives for dissolved oxygen (DO) and pH contained in Chapter 3. Nutrient loading and the resulting ecological responses in the Ventura River, including the Estuary, and its tributaries result in impairments of beneficial uses associated with recreation activities (water contact and non-contact) and aquatic life (warm and cold freshwater habitat; estuarine and wetland habitat; rare, threatened or endangered species; migration of aquatic organisms; spawning, reproduction, and/or early development). The most sensitive beneficial use is the cold water aquatic habitat use and the associated migratory and spawning and early development uses. The Ventura River and its tributaries are home to the Southern California Steelhead, which is an endangered species.

<table>
<tr><th>TMDL Element</th><th>Regulatory Provisions</th></tr>
<tr><td>Numeric Targets</td><td>The DO and pH numeric targets are set equal to their numeric water quality objectives in Chapter 3 of the Basin Plan. The numeric targets for algal and phytoplankton biomass and percent cover are established as a numeric interpretation of the water quality condition that will demonstrate attainment of the narrative water quality objective for biostimulatory substances contained in Chapter 3.

Numeric targets to interpret narrative water quality objectives are based on the California Nutrient Numeric Endpoints (NNE) approach, developed by USEPA Region 9 and the State and Regional Water Quality Control Boards.
<table>
<tr><th>Indicator</th><th>Numeric Target</th><th>Water body</th></tr>
<tr><td>Total Algal Biomass</td><td>150 mg/m^2 chlorophyll a as seasonal average</td><td>Ventura River and Tributaries</td></tr>
<tr><td>Macroalgal Cover (attached & unattached)</td><td>≤ 30 percent as seasonal average</td><td>Ventura River and Tributaries</td></tr>
<tr><td>Phytoplankton Biomass</td><td>20 μg/L chlorophyll a as seasonal average</td><td>Estuary (shallow subtidal area)</td></tr>
<tr><td>Macroalgal Cover</td><td>≤ 15 percent as seasonal average</td><td>Estuary (intertidal and shallow subtidal areas)</td></tr>
<tr><td>Dissolved Oxygen</td><td>≥ 7 mg/L as a daily minimum</td><td>Ventura River, Tributaries and Estuary</td></tr>
<tr><td>pH</td><td>6.5 – 8.5 (instantaneous value)</td><td>Ventura River, Tributaries, and Estuary</td></tr>
<tr><td colspan="3">Biomass and percent cover indicator targets apply during the dry season when algae growth primarily occurs. The seasonal averaging period for algal biomass and percent cover is the dry season of May 1 to September 30. River indicators are averaged over a sampling reach as required by the SWAMP monitoring protocol Bioassessment SOP 02. Estuary macroalgal cover is measured using 3 transects and evaluating percent cover at 10 random points along each transect. Results are reported as a transect average. See methods used in the Bight ’08 Estuarine Eutrophication Assessment (McLaughlin K et al. Southern California Bight 2008 Regional Monitoring Program: Estuarine Eutrophication Assessment. Southern California Coastal Water Research Project. Costa Mesa, CA).</td></tr>
</table>
</td></tr>
<tr><td>Source Analysis</td><td>The source analysis is an estimate of the amount of TN and TP entering the river from point and nonpoint sources based on available information such as discharge nutrient concentration data, land use data, rainfall-runoff models, studies, and literature reviews.

<u>Point sources:</u>

Stormwater runoff discharged via the municipal separate storm sewer system (MS4) contributes a large percentage of the nutrients to the Ventura River and its tributaries (21.3% in dry weather and 28.3% in wet weather). The Ojai Valley waste water treatment plant (WWTP) contributes a large portion of nutrient loading in dry weather (37.6%) but a smaller portion in wet weather (1.7%).

<u>Nonpoint sources:</u>

Horses/livestock and agricultural land uses contribute significant loading in both dry weather (33.5%) and wet weather (36.1%). Open space loading is a</td></tr>
</table>

TMDL Element	Regulatory Provisions
	significant source of nutrients in wet weather (19.1%) and a smaller source of nutrients in dry weather (7.6%). Septic systems are estimated to contribute 4.7% of the annual nutrient load. Groundwater discharge and direct atmospheric deposition to the water surface are responsible for a small portion of the annual load (1.3% and 0.2%, respectively).
Linkage Analysis	The critical condition is the dry season and the linkage analysis for both the Ventura River and Estuary is for dry-weather conditions. Basing the linkage analysis on *dry-weather* conditions is a conservative approach to assessing conditions in the *dry season*. Nutrients are loaded from the watershed to the Ventura River and Estuary in both dry and wet weather, but the nutrients loaded in the dry season are predominately responsible for the algae, eutrophic conditions, and nutrient impairments in the Ventura River and Estuary. <u>Linkage analysis for the river</u> The linkage analysis for the river is based on the River and Stream Water Quality Model (QUAL2K). QUAL2K predicts the nutrient concentrations and algal biomass in the various reaches of the Ventura River based on an estimate of watershed-based loading. The results of the model are used to determine allowable in-stream nutrient concentrations to meet algal biomass targets and to evaluate various source reduction scenarios to set dry-weather load and waste load allocations. <u>Linkage analysis for the Estuary</u> The linkage analysis for the Estuary is based on two lines of evidence that establish the relationship between nutrient loading to the Estuary and the resulting nutrient concentrations and algal biomass in the Estuary. The first approach uses the NNE BATHTUB spreadsheet modeling tool to establish the linkage between nutrient loading to the Estuary and the predicted water quality response, assuming that the open water portion of the Estuary, formed by the closing of the berm in the late summer and early fall, acts like a freshwater reservoir. The second approach uses empirical relationships between nutrient loading and algal biomass (peak macroalgae biomass and annual average chlorophyll a) in estuaries developed as part of a 2008 Southern California Bight Regional Monitoring Program study. Both approaches predict that the current nutrient loading to the Estuary will attain the phytoplankton numeric target. Moreover, the watershed loading reductions required to protect the river will reduce nutrient concentrations delivered to the Estuary and ensure attainment of numeric targets and protection of beneficial uses.

<table>
<tr><th>TMDL Element</th><th>Regulatory Provisions</th></tr>
<tr><td>Allocations</td><td>
Waste load allocations (WLAs) and load allocations (LAs) addressing point and nonpoint sources of nutrients are assigned to discharges to the Ventura River watershed. Because the critical condition for this TMDL is dry weather, and it is the dry-weather loading that results in water quality impairments, the allocations are primarily focused on dry-weather nutrient loading reductions. However, wet-weather WLAs and LAs are assigned as well.

<u>Dry-weather Allocations</u>

The dry-weather WLAs for Ojai Valley WWTP are expressed as seasonal loads. The TN WLA is expressed as a summer dry-weather load based on an estimated 153 summer dry-weather days and a winter dry-weather load based on an estimated 178 winter dry-weather days. The TP WLA is expressed as a dry-weather load based on an estimated 331 dry-weather days. Dry-weather WLAs for the Ojai Valley WWTP are as follows:

<table>
<tr><th>Summer Dry-Weather TN WLA (lb/season)</th><th>Winter Dry-Weather TN WLA (lb/season)</th><th>Dry-Weather TP WLA (lb/season)</th></tr>
<tr><td>8,044</td><td>12,477</td><td>5,799</td></tr>
</table>

At the TMDL reconsideration, the Ojai Valley WWTP allocation may be revised (i.e. increased) if the Ojai WWTP has accepted additional flows from other watershed sources such as septic systems in order to achieve the TMDL. The Ojai WWTP will document and report annually the number, flow and TN load from watershed sources for the Regional Board to consider as part of the TMDL reconsideration.

Dry-weather WLAs for Ventura County MS4 and Caltrans are expressed as daily loads based on an estimated 331 dry-weather days per year. Dry-weather WLAs for Ventura County MS4 and Caltrans are as follows:

<table>
<tr><th>Source Type</th><th>Dry-Weather WLA (lb/day)</th><th>Dry-Weather TP WLA (lb/day)</th></tr>
<tr><td>Dry-weather WLAs for Ventura MS4</td><td>28</td><td>0.5</td></tr>
<tr><td>Dry-weather WLAs for Caltrans</td><td>1.1</td><td>0.11</td></tr>
</table>

The dry-weather WLAs for the general industrial and construction stormwater permittees are equal to the in-stream nutrient concentrations required to meet algal biomass numeric targets. Dry-weather WLAs for general industrial and construction stormwater permittees are as follows:

<table>
<tr><th>Permittee</th><th>TN (mg/L)</th><th>TP (mg/L)</th></tr>
<tr><td>General Industrial Stormwater Permittees</td><td>1.15</td><td>0.115</td></tr>
<tr><td>General Construction Stormwater Permittees</td><td>1.15</td><td>0.115</td></tr>
<tr><td colspan="3">Applied as an annual dry-weather average.</td></tr>
</table>
</td></tr>
</table>

<table>
<tr><th>TMDL Element</th><th>Regulatory Provisions</th></tr>
<tr><td></td><td>
Dry-weather LAs for Agriculture are expressed as daily loads based on an estimated 331 dry-weather days per year as follows:
<table>
<tr><th>Source Type</th><th>Dry-Weather TN LA (lb/day)</th><th>Dry-Weather TP LA (lb/day)</th></tr>
<tr><td>Agriculture</td><td>16</td><td>0.12</td></tr>
</table>
Dry-weather LAs for Horse facilities and intensive livestock operations are expressed as daily loads based on an estimated 331 dry-weather days per year as follows:
<table>
<tr><th>Source Type</th><th>Dry-Weather TN LA (lb/day)</th><th>Dry-Weather TP LA (lb/day)</th></tr>
<tr><td>Horse facilities/Intensive Livestock</td><td>0.6</td><td>0.14</td></tr>
</table>
The dry-weather LA for grazing activities is equal to a 10% percent reduction of the existing TN and TP load. The existing load will be quantified as part of management plans required to implement the TMDL.

<u>Dry- and Wet-weather LAs for OWTS</u>

LAs for OWTS are equal to 7,478 pounds TN per year based on a required 50% reduction in loading. The LAs apply in dry and wet weather. No LAs are assigned to OWTS for TP.

<u>Dry- and Wet-weather WLAs for Other NPDES permittees</u>

Dry-weather WLAs for other NPDES permittees are equal to the in-stream nutrient concentrations required to meet algal biomass numeric targets of 1.15 mg/L TN and 0.115 mg/L TP. Wet-weather allocations are set to attain site-specific nitrogen water quality objectives from Table 3-8. There are no site-specific objectives for Reach 1 or the Estuary, nor are there any “Other NPDES permittees” that discharge to Reach 1 or the Estuary. Thus, there are no wet-weather WLAs assigned to Other NPDES permittees for Reach 1 or the Estuary.

<u>Wet-weather Allocations</u>

Wet-weather allocations for stormwater, agriculture, and horse/livestock sources are set to attain site-specific water quality objectives from Table 3-8 of the Basin Plan, provided in the table below. There are no site-specific objectives for Reach 1 or the Estuary. For Reach 1 and the Estuary, Wet-weather WLAs for stormwater sources are equal to existing water quality in stormwater discharges (maximum TN = 7.4 mg/L) and LAs for agriculture and horse/livestock sources are equal to water quality benchmarks of 10 mg/L nitrate-N + nitrite-N in the Agriculture Waiver.
</td></tr>
</table>

<table>
<tr><th>TMDL Element</th><th>Regulatory Provisions</th></tr>
<tr><td></td><td>
Wet-weather allocations for stormwater, agriculture, and horse/livestock sources are as follows:
<table>
<tr><th>Reach</th><th>Nitrate-N + Nitrite-N (mg/L)</th></tr>
<tr><td>Estuary</td><td>*</td></tr>
<tr><td>Reach 1</td><td>*</td></tr>
<tr><td>Reach 2</td><td>10</td></tr>
<tr><td>Cañada Larga</td><td>10</td></tr>
<tr><td>Reach 3</td><td>5</td></tr>
<tr><td>San Antonio Creek</td><td>5</td></tr>
<tr><td>Reach 4</td><td>5</td></tr>
<tr><td>Reach 5</td><td>5</td></tr>
</table>
*WLAs for stormwater are equal to 7.4 mg/ L TN and LAs for agriculture and horse/livestock sources are equal to 10 mg/L nitrate-N + nitrite-N.

Wet-weather WLAs for the Ojai Valley WWTP are based on existing performance of the facility. Existing performance was calculated as the 90th percentile of the last 12 years of effluent data.

</td></tr>
<tr><td>Margin of Safety</td><td>The sources of uncertainty in this TMDL are related to the selection of the algal biomass target, the relationship between nutrient concentrations and algal biomass in freshwater river systems and estuaries, the estimate of watershed-based nutrient loading, and the model-predicted water quality conditions in the receiving water. These areas of uncertainty are addressed with both an implicit margin of safety that includes conservative assumptions made when estimating watershed-based nutrient loading and the assignment of dry-weather allocations to address a dry-season impairment, and an explicit margin of safety calculated as the difference between the model-predicted maximum concentration in-stream after implementation of reduction scenarios and the desired in-stream concentrations. The explicit margin of safety was calculated as seven percent.</td></tr>
<tr><td>Seasonal Variations and Critical Conditions</td><td>This TMDL addresses impairments that are causing exceedances of the biostimulatory substances water quality objective during the dry season, when algae growth primarily occurs, in the Ventura River, the Estuary and its tributaries. The critical condition is the dry season. Nutrients are loaded from the watershed to the Ventura River and its tributaries, and the Estuary in both dry and wet weather, but the nutrients loaded in the dry season are predominately responsible for the algae, eutrophic conditions, and nutrient impairments. Nutrient</td></tr>
</table>

TMDL Element	Regulatory Provisions
	concentrations present in the river during the winter months are sufficient to support algal growth; however, cofactors in the winter, such as greater flow and lower temperatures, mitigate algal growth in the winter. Also, the typical seasonal succession of primary producers generally shifts in the winter to be dominated by aquatic plants. The watershed nutrient wet-weather loads are generally delivered directly to the ocean and thus do not contribute to exceedance of the biostimulatory substances objective in the river or Estuary, which occurs during the dry season when algae growth primarily occurs. Nonetheless, to protect water quality year-round, wet-weather WLAs and LAs are assigned to meet water quality objectives and/or maintain existing discharge quality.
Monitoring	The TMDL monitoring program consists of three components: 1) receiving water monitoring, 2) discharge monitoring, and 3) optional special studies. All monitoring requirements may be included in subsequent permits or other orders and are subject to Executive Officer approval. <u>Receiving Water Monitoring</u> Responsible parties (Ojai Valley Sanitary District, Ventura County Watershed Protection District, Ventura County, City of Ojai, City of Ventura, Caltrans, and agricultural dischargers) are responsible for developing and implementing a comprehensive monitoring plan to assess numeric target attainment and measure in-stream nutrient concentrations. Responsible parties are encouraged to work together to submit a joint watershed wide plan. Ten years from the effective date of the TMDL, horse intensive livestock, and grazing activities shall participate in the implementation of the watershed-wide monitoring plan or submit their own plan. The monitoring plan should outline a program to sample for algal biomass, algal percent cover, nutrients (total and dissolved), *in situ* water quality parameters (dissolved oxygen, pH, temperature, electrical conductivity), and flow for the river and estuary. Monitoring should include visual observations documenting whether the Estuary is open or closed. The monitoring procedures/methods, analysis, and quality assurance shall be SWAMP comparable, where appropriate. The sampling frequency and locations must be adequate to assess beneficial use condition and attainment of applicable water quality objectives. At a minimum, for algal biomass and percent cover, the monitoring frequency shall be once per month in the dry season (May 1st to September 30th). After two years, if a significant difference between monthly algal biomass measurements is not observed, algal biomass monitoring may be reduced to three times per dry season, during the months of May, July, and September. DO and pH shall be measured continuously for two week periods on a quarterly basis. Continuous monitoring of DO and pH shall occur during the months of May and September in the 2nd and 3rd quarters. . All other parameters shall be monitored monthly. River indicators shall be averaged over a sampling reach as described in the SWAMP monitoring protocol - Bioassessment SOP 02. Estuary macroalgal cover is measured using three transects and evaluating percent cover at 10 random points along each transect. Results are reported as a transect average. See methods used in the Bight '08 Estuarine Eutrophication Assessment

TMDL Element	Regulatory Provisions
	(McLaughlin K et al. Southern California Bight 2008 Regional Monitoring Program: Estuarine Eutrophication Assessment. Southern California Coastal Water Research Project. Costa Mesa, CA). Existing receiving water monitoring conducted under other programs can be leveraged to assist in meeting these monitoring requirements. Responsible parties may build upon existing monitoring programs in the Ventura River watershed when developing the receiving water quality monitoring plan for this TMDL. Receiving water monitoring requirements shall be incorporated into the permit, waste discharge requirements (WDRs), or waiver for each responsible party upon issuance, renewal, or modification. The responsible parties may continue to coordinate a watershed-wide monitoring program to meet this requirement in order to fulfill individual permit, WDR, or waiver requirements. Receiving water monitoring shall continue beyond the final implementation date of the TMDL unless the Executive Officer approves a reduction or elimination of such monitoring. <u>Discharge Monitoring</u> Discharge monitoring will assess attainment of the WLAs and LAs. Discharge monitoring shall be required by regulatory mechanisms used to implement the WLAs and LAs. The monitoring to determine compliance with WLAs and LAs shall be conducted as specified in the Implementation Plan in the following section. The monitoring procedures/methods, analysis, and quality assurance shall be Surface Water Ambient Monitoring Program (SWAMP) comparable, where appropriate, and are subject to Executive Officer Approval. <u>Special Studies</u> Responsible parties within the watershed may conduct optional special studies designed to refine WLAs, LAs, and/or numeric targets. The results of special studies and monitoring may be used to revise numeric targets and allocations, if supported, when the TMDL is reconsidered. The following are potential special studies. ▪ Build upon the algal biomass and total nitrogen relationship established in the 2008 UCSB Study (UCSB, 2009) and collect data to support the establishment of reach-specific relationships. ▪ Confirm the conclusion that an algal biomass target of 150 mg/m^2 is fully protective of aquatic life and minimizes the risk of low DO events. ▪ Collect additional source assessment information and model input data to refine model-predicted relationships between watershed loading and in-stream nutrient concentrations. ▪ Investigate the influence of OWTS on surface water quality. ▪ Collect data to support development of an estuary model, which takes into account tidal influence, the dynamics of macroalgae and phytoplankton growth, residence time, and breaching conditions.

<table>
<tr><th>TMDL Element</th><th>Regulatory Provisions</th></tr>
<tr><td>Implementation Plan</td><td>
<u>WLA Implementation</u>

The regulatory mechanisms used to implement the WLAs include the Ojai Valley WWTP NPDES permit, the Ventura County MS4 permit, the Caltrans MS4 permit, the general industrial storm water permits, the general construction storm water permits, and other NPDES permits. Effluent limits consistent with the assumptions and requirements of the WLAs shall be incorporated into each permit, following the effective date of this TMDL, at the time of permit issuance, modification, or renewal.

<u>Ojai Valley WWTP</u>

The dry-weather TN WLAs for the Ojai WWTP shall be incorporated into the permit as seasonal numeric effluent limitations. The summer effluent limitation shall be equal to the summer dry-weather WLA of 8,044 lbs/season (May 1 to September 30). Compliance with the summer effluent limitation shall be determined by calculating the sum of the products of the average monthly TN concentration, a conversion factor, and the daily flow for each dry-weather day, over the summer season. The winter dry-weather WLA and wet-weather WLA shall be combined into a single concentration-based winter season effluent limitation, calculated as the weighted average of 4 mg/L (the allowable winter dry-weather concentration) and 7.6 (the allowable wet-weather concentration), based on the assumption that there are 178 winter dry-weather days and 34 wet-weather days in a year. The resulting concentration of 4.6 mg/L shall be expressed as a monthly effluent limitation from October 1 to April 30. This calculation is consistent with the assumptions and requirements of the winter dry-weather and wet-weather WLAs.

For TP, compliance with the dry-weather WLA-based effluent limitation shall be determined by calculating the sum of the products of the monthly average TP concentration and the daily flow for each dry-weather day, over an annual period. Wet-weather days shall be excluded from the dry-weather WLA compliance determination. The wet-weather TP WLAs shall be incorporated as effluent limitations, expressed as a daily maximum concentration, to be assessed at a minimum with monthly sampling during months when rain occurs.

Ojai WWTP shall achieve compliance with wet-weather TP WLAs upon incorporation into the permit and shall achieve compliance with dry-weather TP WLAs, winter season TN limits, and summer season TN limits within 10 years of the effective date of the TMDL. Ojai Valley WWTP shall have interim WLAs based on current plant performance.

Ojai Valley WWTP interim dry-weather WLAs (monthly average)

</table>
</td></tr>
</table>

TMDL Element	Regulatory Provisions
	Ventura County MS4 and Caltrans The WLAs for the Ventura County MS4 permittees and Caltrans shall be incorporated into the permits as numeric water quality-based effluent limitations. Permittees may be deemed in compliance with water-quality based effluent limitations if they demonstrate that (1) there are no violations of the water quality-based effluent limitation at the Permittee's applicable MS4 outfall(s); or (2) there is no direct or indirect discharge from the Permittee's MS4 to the receiving water during the time period subject to the water quality-based effluent limitation. Wet-weather numeric effluent limitations shall be expressed as event mean concentrations and shall apply immediately upon issuance, modification, or renewal of the permits. Compliance with wet-weather WLAs shall be assessed at a minimum with two wet-weather sampling events per year. If permittees provide a quantitative demonstration that watershed control measures and BMPs will achieve wet-weather water quality-based effluent limitations, then compliance with wet-weather water quality-based effluent limitations can be determined by implementing those actions, subject to Executive Officer approval. Dry-weather numeric effluent limitations shall be assessed at a minimum with quarterly sampling and shall be attained within 6 years of the effective date of the TMDL. Compliance will only be assessed on the day of sampling. Dry-weather sampling may occur 72 hours after a storm event. Consistent with the assumptions of the dry-weather waste load allocations, compliance with water quality-based effluent limitations may be demonstrated with area-weighted effluent limitations. Area-weighted effluent limitations shall be 0.0025 lb/day/acre TN and 4.7×10^{-5} lb/acre/day TP for the Ventura County MS4, and 0.0042 lb/acre/day TN and 4.2×10^{-4} lb/acre/day TP for Caltrans, derived by dividing the daily loads by the total land use area in the watershed covered by their respective permits (11,085 acres for the Ventura County MS4 and 251 acres for Caltrans, excluding the Coyote Creek subwatershed). Ventura County MS4 permittees and Caltrans shall provide an implementation plan to the Regional Board outlining how they intend to achieve compliance with the WLAs. The report shall include implementation methods and a quantitative analysis of the expected water quality outcomes of the implementation methods, an implementation schedule, proposed interim milestones, and compliance points. The report shall provide reasonable assurance that implementation methods will be sufficient to achieve the WLAs. General Industrial and Construction Stormwater Permittees The dry- and wet-weather WLAs for the general and industrial stormwater permittees shall apply immediately upon permit issuance, modification, or renewal and shall be incorporated into permits as numeric water quality-based effluent limitations. Wet-weather effluent limitations shall be expressed as event mean concentrations and dry-weather effluent limitations shall be expressed as instantaneous maximums. Compliance with wet-weather WLAs shall be assessed

TMDL Element	Regulatory Provisions
	at a minimum with one wet-weather sampling event. Compliance with dry-weather WLAs shall be assessed at a minimum by averaging the results of two grab samples. <u>Other NPDES Permittees</u> The dry- and wet-weather WLAs for other NPDES permittees shall apply immediately upon permit issuance, modification, or renewal of applicable permits and shall be incorporated into permits as numeric effluent limitations. Wet-weather effluent limitations shall be expressed as event mean concentrations and dry-weather effluent limitations shall be expressed as instantaneous maximums. Compliance with wet-weather WLAs shall be assessed at a minimum with one wet-weather sampling event. Compliance with dry-weather WLAs shall be assessed at a minimum with two grab samples. <u>LA Implementation</u> The regulatory mechanisms that will be used to implement the LAs include Basin Plan discharge prohibitions, WDRs, and waivers of WDRs. <u>Agricultural Discharges</u> The LAs for irrigated agricultural lands shall be implemented through the Conditional Waiver of Waste Discharge Requirements for Discharges from Irrigated Lands or other appropriate Regional Board order. Agricultural lands shall achieve compliance with dry- and wet-weather LAs within 6 years of the effective date of the TMDL. To implement the LAs in this TMDL, the monitoring program shall be revised to add representative sites in the lower watershed to monitor runoff from other crop types. In addition, VCAILG shall work with the Regional Board staff to relocate monitoring sites in the upper watershed to better assess potential dry-weather runoff from agriculture. The existing monitoring program for the Agriculture Waiver requires two dry-weather and two wet-weather sampling events. In order to implement the dry-weather LAs, dry-weather sampling may occur 72 hours after a storm event. The revised monitoring program shall be subject to approval by the Executive Officer. To assist in implementation of LAs, area-weighted benchmarks can be applied; if used, they shall be 0.008 lb/day/acre TN and 6.3×10^{-5} lb/acre/day TP, derived by dividing the daily loads by the total agriculture area in the watershed (1971 acres, excluding orchards and the Coyote Creek subwatershed). Order No. 2010-0186 states, “It is expected that source control management practices, such as improved irrigation efficiency and fertilizer management, employed by Dischargers to attain surface Water Quality Benchmarks will reduce loading to groundwater as well.” To implement this TMDL, the VCAILG water quality management plan shall specify that all growers in the Ventura River watershed shall implement nutrient-related source control BMPs. If the LAs are

TMDL Element	Regulatory Provisions
	implemented in another Regional Board order in the future, then that order shall require growers in the Ventura River watershed to implement nutrient-related source control BMPs. The estimated costs for BMPs to control agricultural discharges such as filter strips, mulching, improved irrigation efficiency, nutrient management, manure management, and grazing management are approximately $1031 per acre, $808 per acre, $1784 per acre, $55 per acre-year, $4,500 (average cost of manure bunker), and $1,356 (average cost of a typical watering facility), respectively. Potential sources of financing for these implementation alternatives, such as Clean Water Act section 319(h) grant funding, are discussed in Chapter 4. As discussed in Chapter 4, the U.S. Department of Agriculture Soil Conservation Service and the Resource Conservation Districts provide information on, and assistance in, implementing BMPs. <u>OWTS</u> The LAs for OWTS shall be implemented through discharge prohibitions, WDRs, or waivers of WDRs. Commercial and multifamily OWTS are currently regulated by the Regional Board through WDRs. Single family residential OWTS are currently regulated by the City of Ojai, the City of Ventura, and the County of Ventura, as specified in memorandums of understanding (MOUs) with the Regional Board, in order to implement a waiver of WDRs for single family residential OWTS adopted by the Regional Board in 2004. The MOUs require the Regional Board to evaluate the local agency every five years to ensure their municipal plumbing code and OWTS program is substantially equivalent to any statewide standards adopted pursuant to California Water Code sections 13290 and 13291. The State Water Resources Control Board (State Board) Water Quality Control Policy for Siting, Design, Operation, and Maintenance of Onsite Wastewater Treatment Systems (OWTS Policy) was adopted by the State Board to comply with California Water Code sections 13290 and 13291 on June 19, 2012. The OWTS Policy must be approved by the Office of Administrative Law before it becomes final and in effect. The OWTS in the Ventura River watershed fall under Tier 3 of the OWTS policy and this TMDL establishes the Advanced Protection Management Program for the watershed. The geographic area for the Advanced Protection Management Programs to implement this TMDL shall initially be the entire Ventura River watershed. The Regional Board will work with local agencies to determine which existing OWTS or areas of OWTS are contributing to the overall loading from OWTS to the Ventura River and its tributaries. Areas found not to be contributing to the overall loading may be removed from the Advanced Protection Management Program as approved in a Local Agency Management Program. Existing OWTS are required to be upgraded or modified to enhance their nitrogen removal or meet other requirements of the Advanced Protection Management Program if it is determined they are contributing to the impairment, and are subsequently covered under approved special provisions of a Local Agency

TMDL Element	Regulatory Provisions
	Management Program, or the Regional Board issues subsequent orders requiring upgrades or modifications. Existing OWTS will remain regulated by existing MOUs and future Local Agency Management Programs until the above determination is made and subsequent upgrades are required. New or replacement OWTS installations, as defined by the OWTS Policy upon its becoming effective, that are within the Advanced Protection Management Program area, shall meet the supplemental treatment requirements for nitrogen per Tier 3 of the OWTS Policy. The Regional Board will evaluate the existing MOUs and any future submittal of a Local Agency Management Program under the OWTS Policy with the City of Ventura, the City of Ojai, and the County of Ventura to determine if their OWTS programs need to be updated to reflect the OWTS Policy, or if additional changes are needed to implement the LAs. OWTS dischargers shall achieve compliance with dry- and wet-weather LAs within 10 years of the effective date of the TMDL. <u>Horse and Intensive Livestock Activities</u> The LAs for horse and intensive livestock activities shall be regulated by WDRs, waivers of WDRs, or other regulatory mechanisms in accordance with the Nonpoint Source Implementation and Enforcement Policy (NPS Policy). The Regional Board will determine which horse and intensive livestock activities shall be subject to the WDRs, waivers of WDRs or other regulatory mechanisms during their development based on factors that may include, but are not limited to, type of operation, density of animals, and risk to water quality. Horse and intensive livestock activities shall be required to develop management plans for Executive Officer approval and implement management measures identified in management plans to attain LAs. Compliance with LAs will be demonstrated with monitoring approved by the Executive Officer of the Regional Board through the monitoring program developed as part of the waiver, WDR, or other regulatory mechanism. Monitoring may consist of documentation of BMP implementation, and may include water quality monitoring as needed. Horse and intensive livestock activities shall achieve compliance with dry- and wet-weather LAs within 10 years of the effective date of the TMDL. <u>Grazing Activities</u> The LAs for grazing activities shall be regulated by WDRs, waivers of WDRs, or other regulatory mechanisms in accordance with the NPS Policy. Because the dry-weather load from grazing activities has not been quantified as of the effective date of this TMDL, and dry-weather LAs are based on a 10% reduction of existing dry-weather load, grazing activities shall be required to either conduct monitoring or utilize other acceptable data or studies as approved by the Executive Officer to determine baseline dry-weather pollutant load caused by grazing activities, unless the Regional Board has already quantified the existing dry-weather pollutant load. In addition, grazing activities may conduct baseline

TMDL Element	Regulatory Provisions
	monitoring to confirm wet-weather pollutant loading. Baseline monitoring shall be required by WDRs, waivers of WDRs, or other regulatory mechanism, if necessary. Baseline monitoring may consist of water quality monitoring of sites impacted by grazing and compared to water quality monitoring from unimpacted natural background sites. If it is determined that there are no water quality impacts due to dry- and/or wet-weather pollutant loading from grazing in the Ventura River watershed, then the TMDL may be revised to adjust the source assessment and allocation scenario when the TMDL is reconsidered. If it is determined that there are water quality impacts due to dry- and/or wet-weather pollutant loading from grazing in the Ventura River watershed, then grazing activities shall develop management plans for approval by the Executive Officer and implement management measures identified in management plans to attain LAs. Compliance with LAs will be demonstrated with monitoring approved by the Executive Officer of the Regional Board through the monitoring program developed as part of the waiver, WDR, or other regulatory mechanism. Monitoring may consist of documentation of no discharge due to BMP implementation, and may include water quality monitoring during conditions under which discharge may occur, including wet weather. Grazing activities shall achieve compliance with dry- and wet-weather LAs within 10 years of the effective date of the TMDL.

Table 7-35.2. Ventura River, Ventura River Estuary, and Tributaries Algae, Eutrophic Conditions and Nutrients TMDL: Implementation Schedule

Task	Due Date
Submit results of optional special studies	4 years after effective date of TMDL
Reconsider TMDL to revise numeric targets and allocations if supported by special studies or other changes in the watershed.	5 years after effective date of TMDL
Ojai Valley Sanitary District	
Wet-weather and interim dry-weather WLAs apply	Effective date of TMDL
Submit receiving water monitoring plan to assess numeric target attainment and measure in-stream nutrient concentrations	1 year after effective date of TMDL
Initiate receiving water monitoring plan	90 days after approval of monitoring plan
Discharge monitoring plan incorporated into permit	Upon permit adoption, renewal, or modification
Dry-weather WLA apply	No later than 12 years after effective date of TMDL*
Ventura County MS4 Permittees and Caltrans	
Wet-weather WLAs apply	Effective date of TMDL
Discharge monitoring plan incorporated into permit	Upon permit adoption, renewal, or modification
Submit monitoring plan to assess numeric target attainment and measure in-stream nutrient concentrations.	1 year after effective date of TMDL
Initiate receiving water monitoring plan	90 days after approval of monitoring plan
Submit implementation plan to achieve compliance with the WLAs. The plan shall include implementation methods, an implementation schedule, proposed interim milestones, and compliance points.	2 years after effective date of TMDL
Dry-weather WLAs apply	6 years after effective date of TMDL
General Industrial and Construction Stormwater Permittees	
Wet-weather and dry-weather WLAs apply	Effective date of TMDL
Discharge monitoring plan incorporated into permit	Upon permit adoption, renewal, or modification
Other NPDES Permittees	
Wet-weather and dry-weather WLAs apply	Effective date of TMDL
Discharge monitoring plan incorporated into permit	Upon permit adoption, renewal, or modification

Task	Due Date
Agricultural Discharges	
Discharge monitoring plan incorporated into Agriculture Waiver or other order or waiver	Upon adoption, renewal, or modification
Submit monitoring plan to assess numeric target attainment and measure in-stream nutrient concentrations.	1 year after effective date of TMDL
Initiate receiving water monitoring plan	90 days after approval of monitoring plan
Wet-weather and dry-weather LAs apply	6 years after effective date of TMDL
Onsite Waste Water Treatment Systems	
Regional Board staff and Ventura County will work to determine areas of OWTS to be included in an Advanced Protection Management Program area and a plan for a 50 percent reduction of loading from OWTS in these areas	3 years from the effective date of the TMDL
Wet-weather and dry-weather LAs apply	10 years after effective date of TMDL
Horse/ Intensive Livestock Activities	
Discharge monitoring plan submitted as part of waiver, WDR, or other regulatory mechanism requirement or in response to Regional Board order	5 years after effective date of TMDL
Conduct receiving water monitoring to assess numeric target attainment and measure in-stream nutrient concentrations	10 years after effective date of TMDL
Wet-weather and dry-weather LAs apply	10 years after effective date of TMDL
Grazing Activities	
Baseline monitoring plan or acceptable existing data or studies to determine baseline dry-weather pollutant load submitted as part of waiver or WDR requirement or in response to Regional Board order, unless the Regional Board has quantified the existing pollutant load	2 years after effective date of TMDL
Results of baseline monitoring submitted, if necessary	18 months after approval of baseline monitoring plan
Discharge monitoring plan submitted as part of waiver, WDR, or other regulatory mechanism requirement or in response to Regional Board order	5 years after effective date of TMDL
Conduct receiving water monitoring to assess numeric target attainment and measure in-stream nutrient concentrations	10 years after effective date of TMDL
Wet-weather and dry-weather LAs apply	10 years after effective date of TMDL

* If TMDL reconsideration results in more stringent WLAs, then the implementation schedule for OVSD may be extended, if necessary, by only the amount of time required to upgrade treatment processes to meet the more stringent WLAs.

1. INTRODUCTION

The Ventura River Estuary and the Ventura River (including its tributaries), located in Ventura County, are identified on the 1998, 2002, 2006, and 2010 Clean Water Act (CWA) Section 303(d) list of impaired waterbodies due to algae, eutrophic conditions, low dissolved oxygen, and nitrogen (Table 1-1). The CWA requires the development of Total Maximum Daily Loads (TMDLs) to restore impaired waterbodies to fully support their beneficial uses. This document provides the background information used by the California Regional Water Quality Control Board, Los Angeles Region (Los Angeles Regional Board) in the development of the TMDL for Algae, Eutrophic Conditions, and Nutrients in the Ventura River and its Tributaries.

Table 1-1 CWA Section 303(d) list of algae, eutrophic conditions, and nitrogen impairments in the Ventura River and its tributaries

Waterbody Name	Pollutant(s)
Ventura River Estuary	Algae, Eutrophic
Ventura River Reach 1 and 2 (Estuary to Weldon Canyon)	Algae
San Antonio Creek	Nitrogen
Cañada Larga	Low Dissolved Oxygen

As documented in this staff report, the algae and nutrient-related impairments are caused by excessive loading of nutrients, particularly nitrogen and phosphorus to Ventura River and its tributaries.

1.1 Regulatory Background

Section 303(d) of the Clean Water Act (CWA) requires that "Each State shall identify those waters within its boundaries for which the effluent limitations are not stringent enough to implement any water quality standard applicable to such waters." The CWA also requires states to establish a priority ranking for waters on the 303(d) list of impaired waters and establish TMDLs for such waters.

The elements of a TMDL are described in 40 CFR sections 130.2 and 130.7 and Section 303(d) of the CWA, as well as in the U.S. Environmental Protection Agency guidance (U.S. EPA, 2000a). A TMDL defined as the "sum of the individual waste load allocations for point sources and load allocations for nonpoint sources and natural background" (40 CFR section 130.2) such that the capacity of the waterbody to assimilate pollutant loadings (the Loading Capacity) is not exceeded. TMDLs are also required to account for seasonal variations, and include a margin of safety to address uncertainty in the analysis.

States must develop water quality management plans to implement the TMDL (40 CFR section 130.6). The U.S. EPA has oversight authority for the 303(d) program and is required to review and either approve or disapprove the TMDLs submitted by states. If the

U.S. EPA disapproves a TMDL submitted by a state, U.S. EPA is required to establish a TMDL for that waterbody.

A schedule for development of TMDLs in the Los Angeles Region was established in a consent decree (Heal the Bay Inc., et al. v. Browner C 98-4825 SBA) approved on March 22, 1999. The consent decree combined waterbody pollutant combinations in the Los Angeles Region into 92 TMDL analytical units. In accordance with the consent decree, this TMDL addresses the waterbodies in analytical unit 88. This document summarizes the analyses performed and presents the TMDL for Algae, Eutrophic Conditions, and Nutrients in the Ventura River and its Tributaries.

1.2 Elements of a TMDL

There are seven elements of a TMDL. Sections 2 through 7 of this document are organized such that each section describes one of the elements, with the analysis and findings of this TMDL for that element. The elements are:

- Section 2: Problem Identification. This section reviews the data used to add the waterbody to the 303(d) list, and summarizes existing conditions using that evidence along with any new information acquired since the listing. This element identifies those beneficial uses that are not supported by the waterbody; the water quality objectives (WQOs) designed to protect those beneficial uses; and summarizes the evidence supporting the decision to list each reach, such as the number and severity of exceedances observed.
- Section 3: Numeric Targets. The numeric targets for this TMDL are based upon the WQOs described in the Basin Plan.
- Section 4: Source Assessment. This section develops the quantitative estimate of nutrient loading from point sources and nonpoint sources to the Ventura River and its tributaries.
- Section 5: Linkage Analysis. This analysis shows how the sources of pollutants discharged to the waterbody are linked to the observed conditions in the impaired waterbody.
- Section 6: Pollutant Allocations. Each pollutant source is allocated a quantitative load that it can discharge to meet the numeric targets. Point sources are assigned waste load allocations (WLAs) and nonpoint sources are assigned load allocations (LAs). Allocations are designed such that the waterbody will not exceed numeric targets for any of the compounds or related effects. Allocations are based on critical conditions, so that the allocated pollutant loads may be expected to remove the impairments at all times.
- Section 7: Implementation and Monitoring. This section describes the plans, regulatory tools, or other mechanisms by which the WLAs and LAs may be achieved. The TMDL provides cost estimates to meet the WLAs and LAs. The TMDL includes a monitoring program to assess TMDL effectiveness and attainment of water quality standards. It also describes special studies to address

uncertainties in assumptions made in the development of this TMDL and the process by which new information may be used to refine the TMDL.

1.3 Environmental Setting

The Ventura River watershed (Figure 1-1) is located in the northwestern portion of Ventura County with a small portion in the southeastern portion of Santa Barbara County. The watershed drains a fan-shaped area of about 220 square miles with an elevation from 6,000 feet to sea level. The Ventura River has several major tributaries, including Matilija Creek, North Fork Matilija Creek, San Antonio Creek, Coyote Creek and Cañada Larga. Matilija creek (15 miles) drains the Santa Ynez Mountains as it flows to the Matilija Reservoir and the Matilija Dam. The creek continues below the dam for about one half mile before it joins North Fork Matilija Creek. North Fork Matilija Creek, which is about 12 miles long, generally follows Highway 33 in the Los Padres National Forest until it joins Matilija Creek.

The Ventura River starts at the confluence of Matilija Creek and North Fork Matilija Creek. The Ventura River then flows for about 16 miles in a southerly direction to the estuary and the Pacific Ocean. The Ventura River has intermittent direct discharge to the ocean; longshore transport of sand can cause a sand bar to form at the mouth of the estuary in the late summer and early fall.

The Ventura River Estuary extends from the ocean to approximately 150 meters upstream of the railroad bridge based on tidal influence. The Estuary includes an open water area that is separated from the ocean by a berm that forms during the dry season. The berm is breached during storm events and slowly rebuilds through the summer, sometimes not fully building until August or September. The Estuary is flushed by tides when the berm is open and is dominated by slightly brackish to freshwater when the berm is closed (Ventura River Watershed State of the Watershed Report).

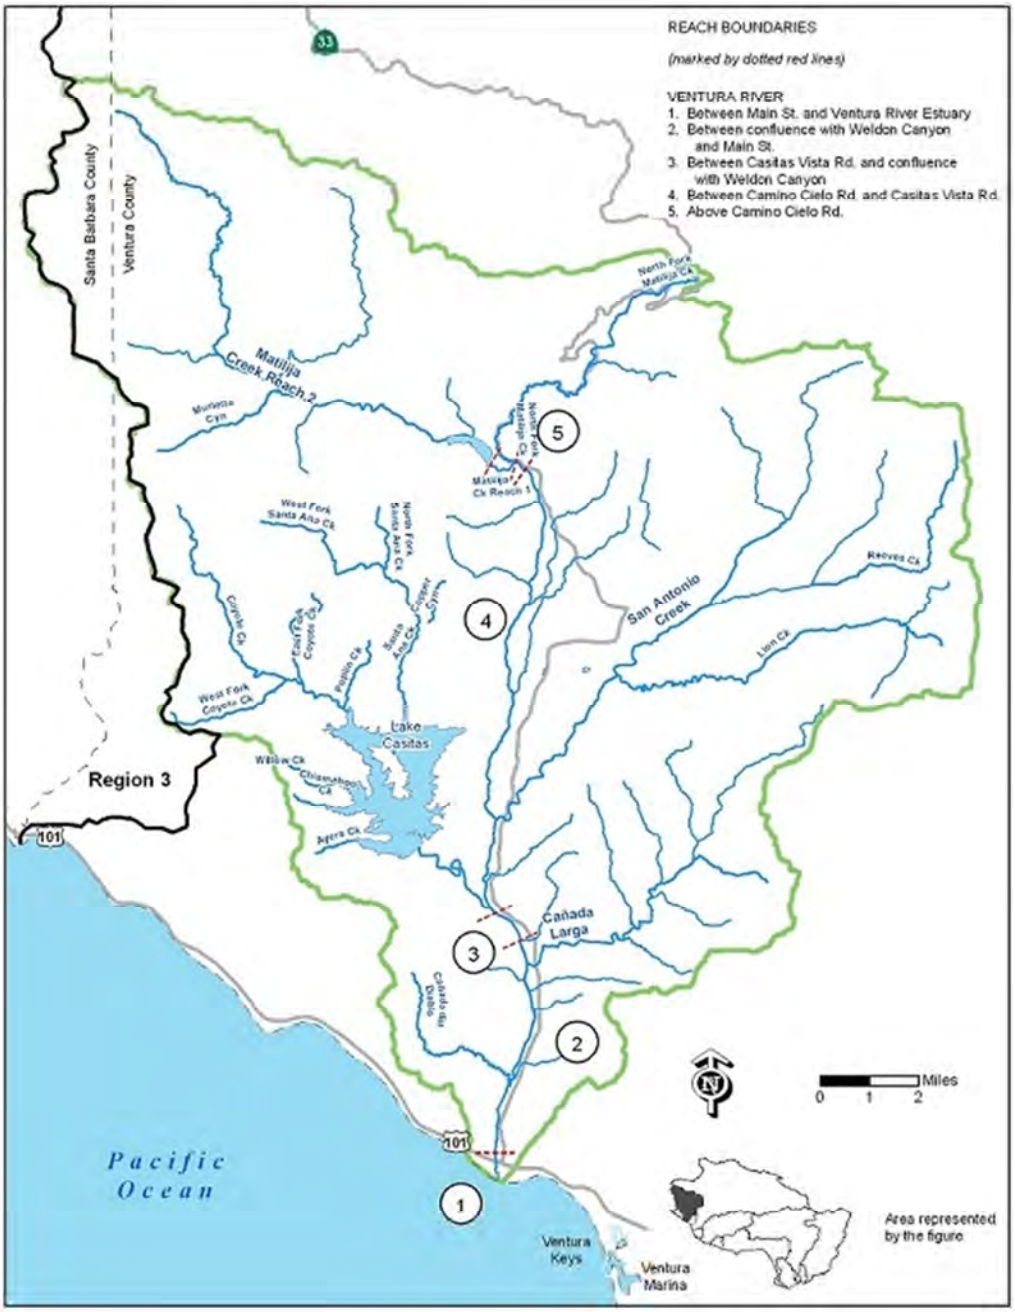

Figure 1-1 Major Surface Waters in Ventura River Watershed

The watershed topography is characterized by rugged mountains in the upper basins transitioning to less steep areas and valleys in the lower watershed. The gradient in the watershed ranges from about 150 feet per mile at the headwaters to about 40 feet per mile near mouth of the river. The U.S. Bureau of Reclamation classifies the watershed topography as fifteen percent valley, forty percent foothill, and forty-five percent mountain. The highest point in the watershed is at 6,025 feet in the Santa Ynez Mountains.

There are two reservoirs within the watershed: Lake Casitas and Matilija Reservoir. Lake Casitas serves as an important source of municipal supply water and is a popular recreation

area. The Matilija Reservoir was originally constructed in 1947 to supply water for both agriculture and municipal uses and provide limited flood control. However, over the years large amounts of sediment has been trapped behind the dam and the storage capacity has been significantly reduced. Today the current dam capacity is estimated at less than 500 acre-feet (Tetra Tech, 2012). In 1998 studies were initiated to investigate the effect of removing the dam and the *Matilija Dam Ecosystem Restoration Project* was developed. This project aims to remove both Matilija Dam and the sediment accumulated behind the dam. Removal of the dam would eliminate a barrier to fish passage on Matilija Creek and facilitate the migration, spawning, and rearing of southern steelhead trout.

1.3.1 Land Use

Based on the Southern California Association of Governments (SCAG) Geographic Information System (GIS) database, eighty-five percent of the land use in the Ventura River watershed (Figure 1-2) is classified as open space and approximately one half of the watershed lies within the Los Padres National Forest. The Matilija Wilderness area, which is managed by the Los Padres National Forest and Ojai Ranger District, is an open space area with access only allowed by foot on marked trails. The remainder of the forest area in the watershed is designated as semi-primitive and has roads leading to recreation areas.
Agricultural land use is the second largest in the watershed at 4.5 percent of the watershed area. The developed area of the watershed is very limited compared to the open space areas, high density and low density residential land uses account for 1.9 and 2.9 percent, respectively. The cities of Ojai and Ventura are the largest urban areas in the watershed and the communities of Casitas Springs, Foster Park, Oak View, Valley Vista, Mira Monte, Meiners Oaks, Upper Ojai and Live Oak Acres are within the unincorporated Ventura County. Industrial areas in the watershed are generally used for oil production and mining and account for 2.1 percent of the watershed area. The remaining land uses (Public Facilities, Recreation, Commercial, Education Institutions, Horse Ranch/Livestock, Transportation, and Mixed Urban) each account for less than 1 percent of the land use within the watershed (Table 1-2).

Table 1-2 Land Uses of Ventura River Watershed

Land Use	Area (Square miles)	Percentage (%)
Open Space	186	84.6
Agriculture	9.98	4.5
Low Density Residential	6.33	2.9
Industrial	4.65	2.1
Water	4.17	1.9
High Density Residential	4.08	1.9
Public Facilities	1.17	0.5

Commercial	0.70	0.3
Education Institutions	0.59	0.3
Horse Ranch/Livestock	0.57	0.3
Transportation	0.39	0.2
Mixed Urban	0.02	<0.1
Total of all classes	**220**	**100**

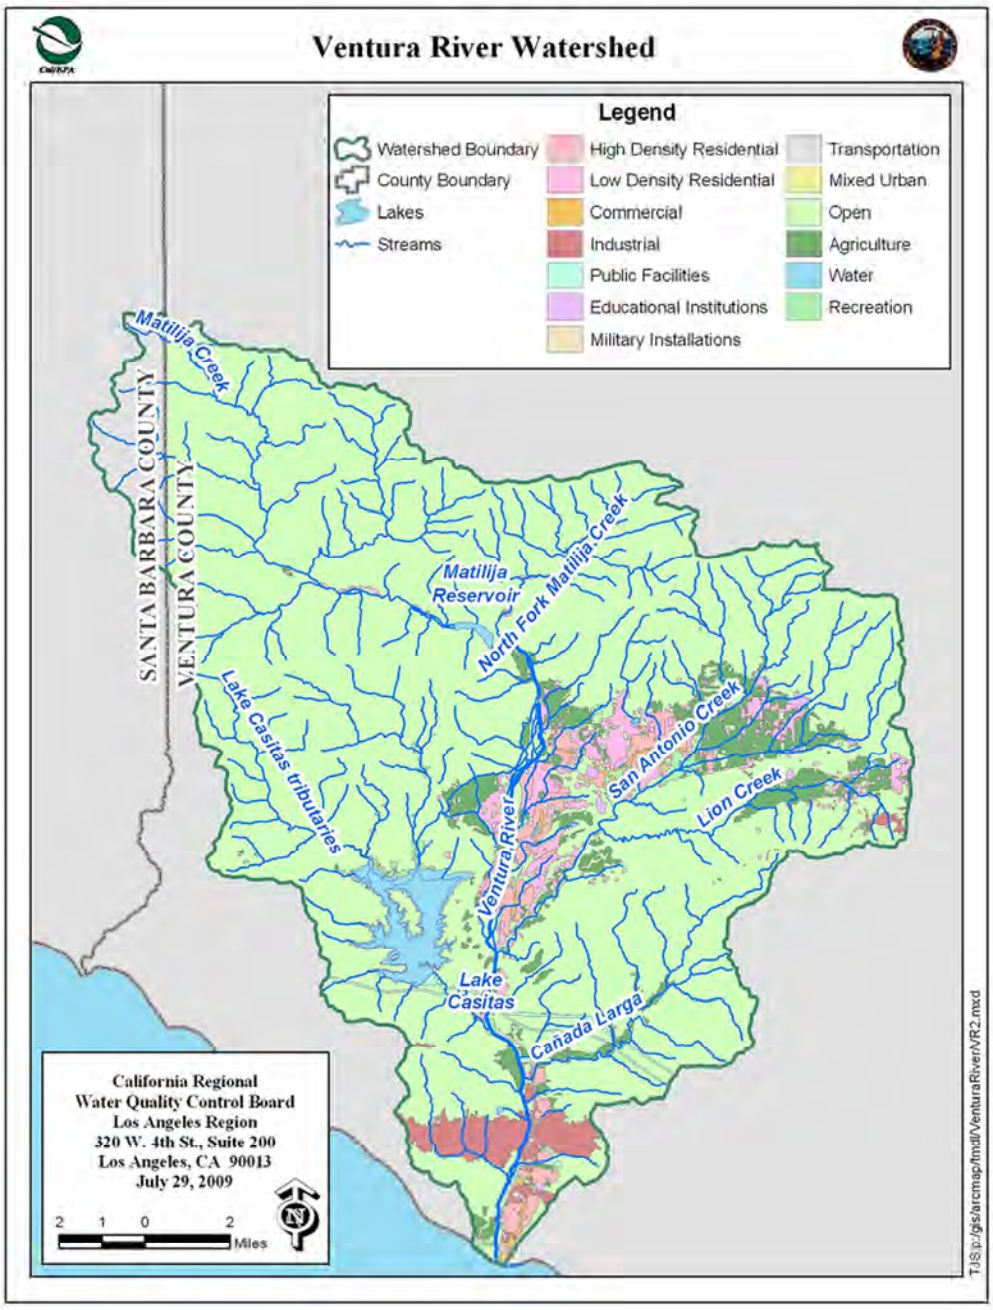

Figure 1-2 Land Uses of the Ventura River Watershed

1.3.2 Hydrology

Flow in the Ventura River varies seasonally due to the Mediterranean climate pattern of wet cool winters from November through March and dry warm summers from April through October. Annual rainfall can vary considerably from year to year. Figure 1-3 presents the annual rainfall from 2005 to 2010 as measured by Ventura County Watershed Protection District at Ojai County Fire Station.

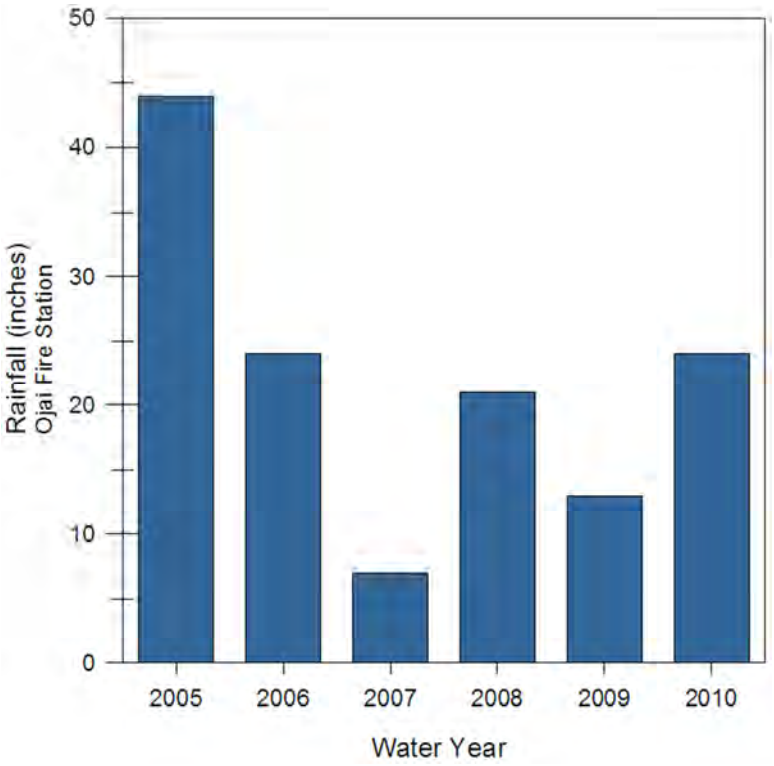

Figure 1-3 Annual rainfall at Ojai County Fire Station

High flows predominate during the rainy season, starting in winter through early spring. For example, Figure 1-4 presents flow in the Ventura River at Foster Park from October 2000 – 2008; peak flows occur after winter storm events and the flows decline to very low levels, less than 1 cfs, during the dry season. However, this pattern is mitigated in the lower Ventura River by effluent from the Ojai Valley Waste Water Treatment Plant (WWTP), which constitutes a majority or, at times, all of the flow in this section of the river during the summers and fall of dry years. The red hydrograph is the flow from Ojai Valley WWTP.

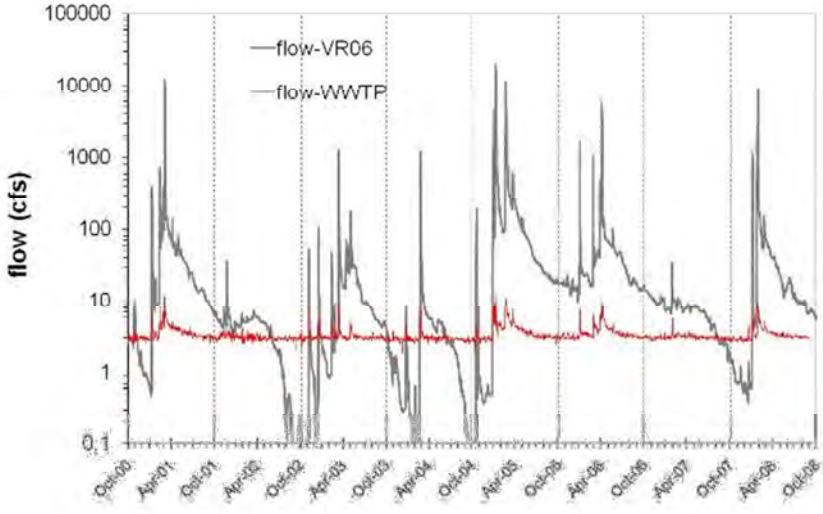

Figure 1-4 Stream Flow in Ventura River at Foster Park and Effluent Discharge from Ojai Valley WWTP (Klose et al., 2009)

In addition to natural variations in flow, based on annual rainfall, flow regimes in the Ventura River have been altered to support water supply. Typically there is perennial flow from the headwaters to the Robles Diversion Dam, which is located about two miles downstream from the Matilija Dam. The Robles Diversion Dam was built in 1958 and is used to divert water from the Ventura River into Lake Casitas via the Robles-Casitas Canal. The flow downstream of the Robles Diversion Dam to the confluence with San Antonio Creek is intermittent, particularly during the dry summer months. Geologic features in the area of Casitas Springs (lower part of Reach 4) causes rising groundwater and provides perennial base flow in the river. The flow in the river is disrupted at Foster Park due to subsurface diversions and groundwater extraction. However, the river flow below Foster Park to the estuary increases due to effluent discharges from the Ojai Valley WWTP.

2. PROBLEM IDENTIFICATION

This section provides an overview of the impairments of the Ventura River Estuary and Ventura River by nutrients and related effects. Subsection 2.1 provides background information on nutrient enrichment. Subsection 2.2 presents the numeric and narrative water quality objectives and beneficial uses applicable to the Ventura River and Estuary. Subsection 2.3 provides a review of the information used by the Regional Board to list the Ventura River and Estuary, San Antonio Creek and Cañada Larga for algae, eutrophic conditions, nitrogen, and low dissolved oxygen. Additional data, where available, were used to assess the current condition of the waterbodies.

2.1 Nutrient Enrichment Problems in Rivers & Estuaries

Nutrients, including nitrogen (N) and phosphorus (P), are essential for plant growth and are often important limiting nutrients in aquatic environments. However, in situations of nutrient enrichment, the nutrients N and P are no longer limiting; in fact, they are readily available in the waterbody, which causes an increase in primary production and eutrophication. Eutrophication is defined by increased nutrient loading to a waterbody and the subsequent ecological response. Accelerated input of nutrients into rivers and estuaries leads to degraded waterbody conditions. Symptoms of eutrophication in rivers and estuaries are listed below.

- Increased algal biomass (macroalgae and phytoplankton)
- Reductions in dissolved oxygen (hypoxia)
- Alterations in algal species composition
- Alterations in food resources and habitat structure
- Harmful algal blooms

The relationship between nuisance algae growth and nutrient enrichment in creek and stream systems has been well-documented in the literature (Dodds and Welch, 2000; Biggs, 2000; Busse et al., 2006). Eutrophication and nutrient enrichment problems rank as one of the top causes of impairment to the nation's waters (EPA Rivers Criteria tech guide 2000 and NOAA Estuary report 1999). The problems associated with these impacts can range from a recreational nuisance to serious aquatic life and public health concerns. For example, high amounts of algal biomass and other aquatic plants interfere with swimming or wading, angling, and/or aesthetic enjoyment of the waterbody and impair the recreational beneficial uses. The aquatic life impacts of eutrophication can include fish kills, lowered fishery production, loss or degradation of important habitats (e.g. seagrass, cobble/gravel niche space), and smothering of benthic organisms (NOAA 1999 and EPA CADDIS).

There are many complex ways in which excess nutrient loads can impact beneficial uses. The conceptual models in Figures 2-1 and 2-2 outline the interactions between nutrients and biological responses in streams and estuaries, respectively. There are numerous overlapping physical, chemical, and biological factors that affect how a waterbody responds to increased nutrient loading. For example, nutrients, temperature, and light often interact together and influence processes within the aquatic ecosystem. The models below

work to demonstrate the interaction and influence of various factors and to assess pathways that are contributing to the impairment of beneficial uses.

Increased nutrient loading into the stream can result in increased algal growth (Figure 2-1). The high levels of algal biomass through respiration (consumption of oxygen and production of carbon dioxide) and photosynthesis (consumption of carbon dioxide and production of oxygen) can cause significant increases in diurnal dissolved oxygen (DO) and pH swings and result in decreased overall DO (Welch and Jacoby 2004, Anderson and Carpenter, 1998). Streams impacted by high levels of algal biomass will often demonstrate supersaturated DO concentrations and high pH values in late afternoon and minimum DO and pH values in early morning (Anderson Carpenter, 1998). Low overnight DO concentrations can have considerable negative impacts on fish and in extreme cases the overnight low DO concentrations can be lethal for fish.

Adequate concentrations of dissolved oxygen are critical for the survival of fish and cold water fishes like steelhead have even greater oxygen requirements as compared to warm water fish. Decreased oxygen levels will increase the physiological stress of fish because their metabolic demands are not being met. This can impact growth and development at different steelhead life stages including eggs, alevins, and fry, as well as the swimming, feeding, and reproductive ability of juvenile and adult fish (Carter, 2005, Bjornn and Reiser, 1991).

2.1.1 Risk Cofactors for Rivers

The combination of increased nutrient loading and other factors, referred to as “cofactors”, together cause impacts (i.e. elevated algal growth, decreased DO, high pH), which lead to beneficial use impairments. The risk cofactors, in conjunction with nutrient loads, contribute to the degraded conditions manifested by the Ventura River watershed. Risk cofactors include light, temperature, flow, and canopy cover. Key cofactors in the Ventura River system are discussed below.

Riparian habitat serves several functions in stream systems including, providing shade and moderating water temperature. Riparian areas also serve to stabilize banks, prevent erosion and add to overall stream channel complexity through inputs of woody debris and aid in pool formation (Ventura River Steelhead Restoration Plan, 1997). Reductions in riparian habitat have associated reductions in shade and increased water temperatures, which promotes the growth of algae and influences changes in DO and pH. Furthermore, channel alterations including erosion, straightening, and hardening prevent the river from maintaining productive stable stream banks and disconnect the river from riparian habitat thereby preventing an important riparian function - filtering runoff.

Also, decreased flow conditions are more susceptible to high temperatures and low DO and long time periods between scour events.

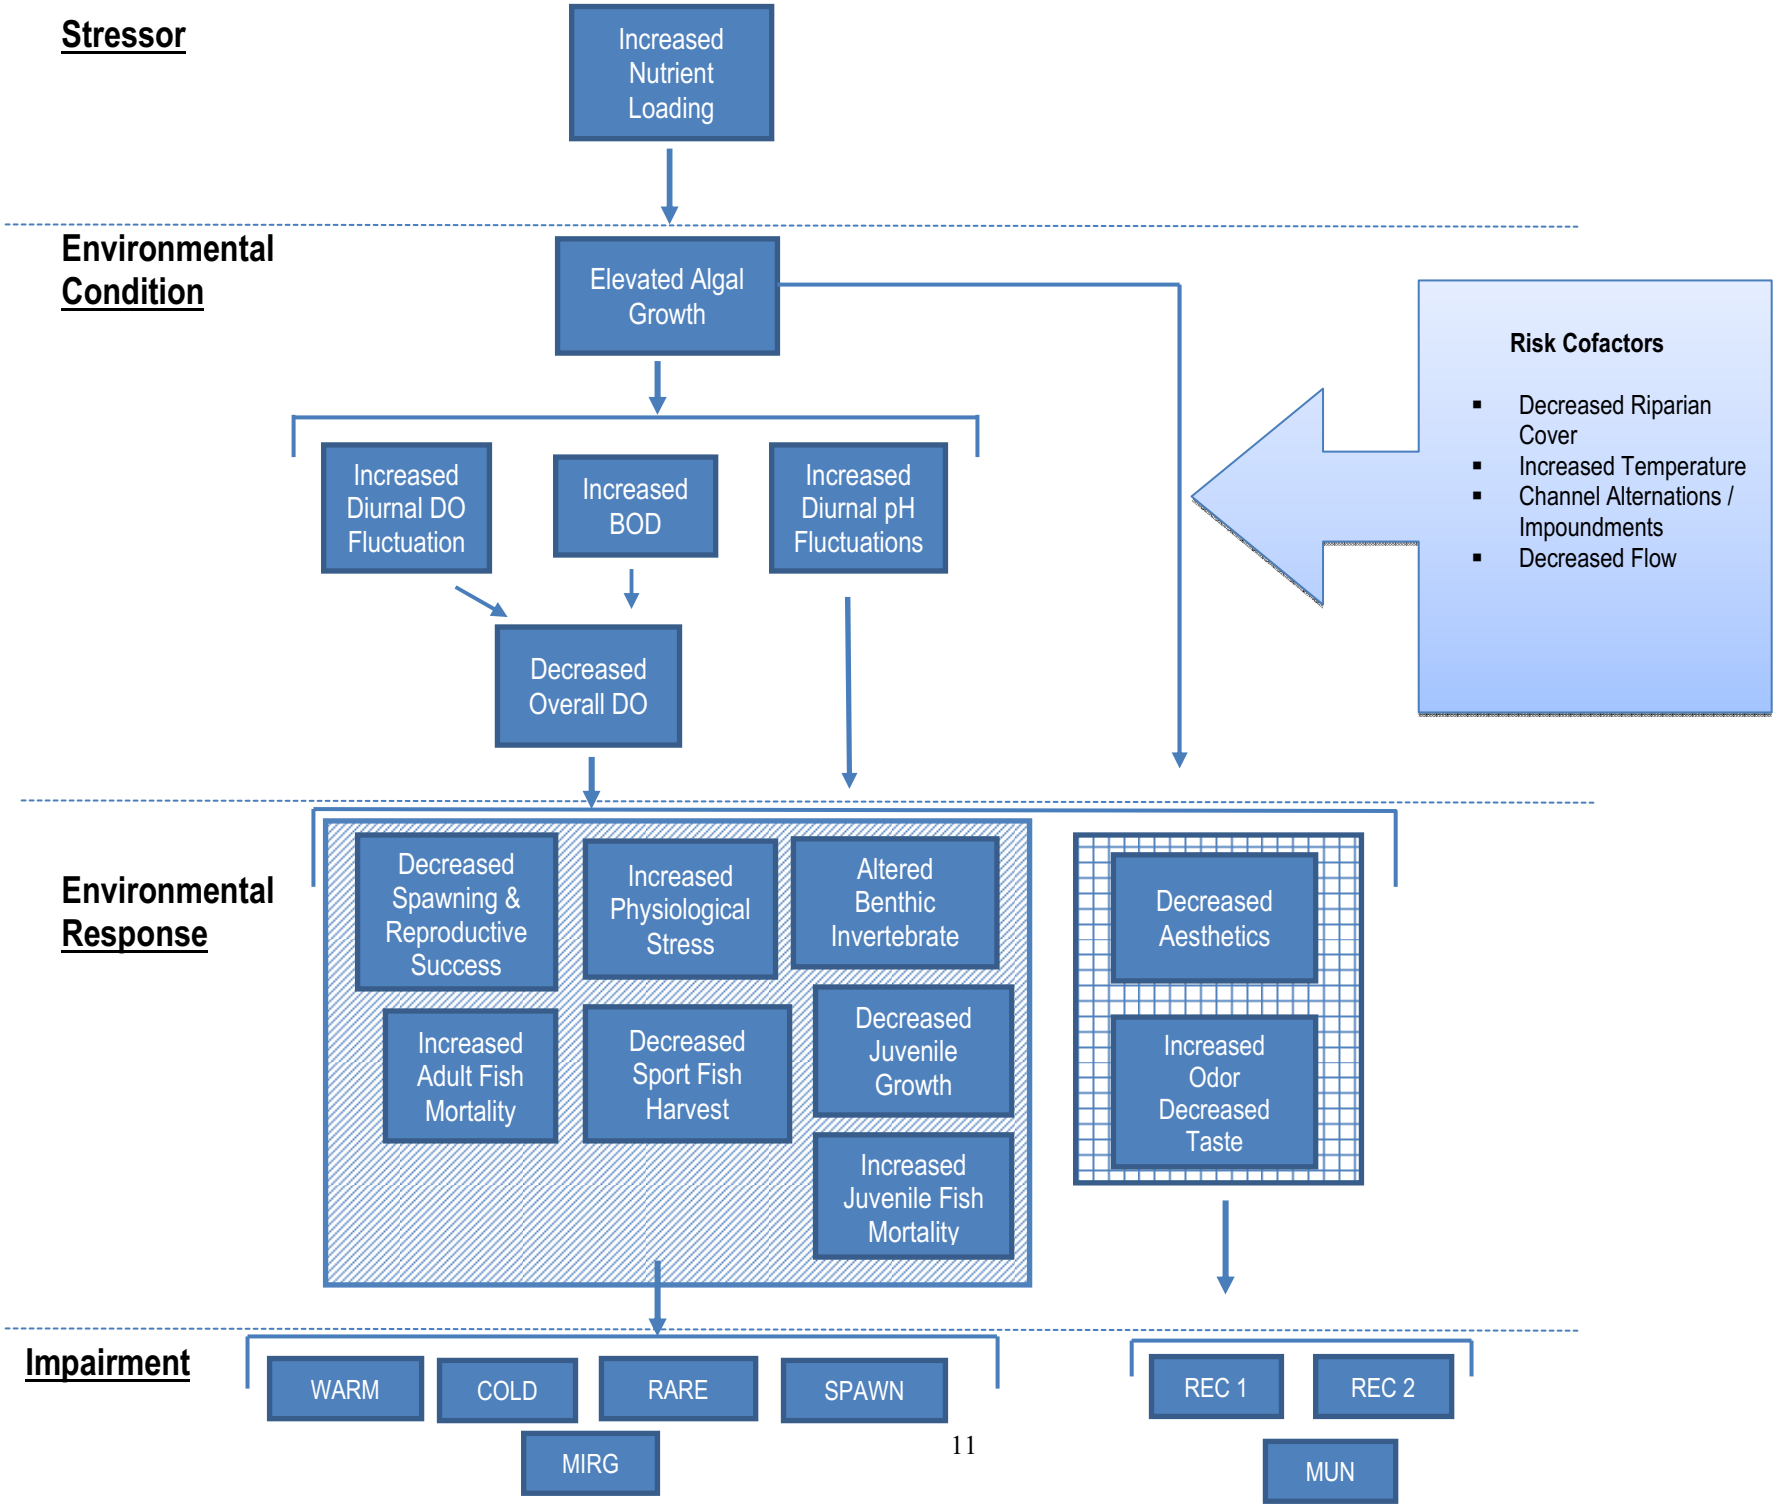

Figure 2-1 Conceptual Model for Rivers

Similar to river systems the immediate response to increased nutrient loading in estuaries is increased algal growth and potential changes in the primary producer community (Figure 2-2). As nutrient levels increase, the shallow subtidal conditions become more favorable for epiphytes (algae growing on the surface of other aquatic plants), and/or macroalgae. In deeper estuaries, phytoplankton biomass increases. This increased algal biomass (i.e. available organic matter) has effects on the biogeochemical cycling in the estuary's sediments and water. These effects include increased respiration in the sediment and water, greater frequency and duration of low dissolved oxygen conditions, and increased ammonium and sulfide in sediment pore water. The poor habitat conditions cause negative impacts on benthic organisms and higher level consumers including other invertebrates, fish, and birds (Green, 2011).

2.1.2 Risk Cofactors for Estuaries

There are also cofactors for estuaries that influence how the waterbody responds to increased nutrient loading and the potential risk of beneficial use impairment. These co-factors include light, temperature, mixing, and residence time. For example, estuaries with lower residence time and more frequent flushing generally accumulate less organic matter and maintain sufficient oxygen levels. Also, the effects of nutrient loading on macroalgal cover and biomass are strongly influenced by the hydrologic connection between the estuary and ocean (Sutula, 2011). Estuaries perennially connected to the ocean are expected to have decreased effects (i.e. changes to water and sediment physiochemical parameters) from macroalgae because these effects generally decrease with increased water depth. However, intertidal and shallow subtidal areas are more likely to be affected by macroalgae mats because there is a greater amount of algal biomass relative to the volume of water (Sutula, 2011). Finally, as in rivers, the availability of light and increased water temperatures promotes algal growth, which can influence changes in estuary oxygen and pH.

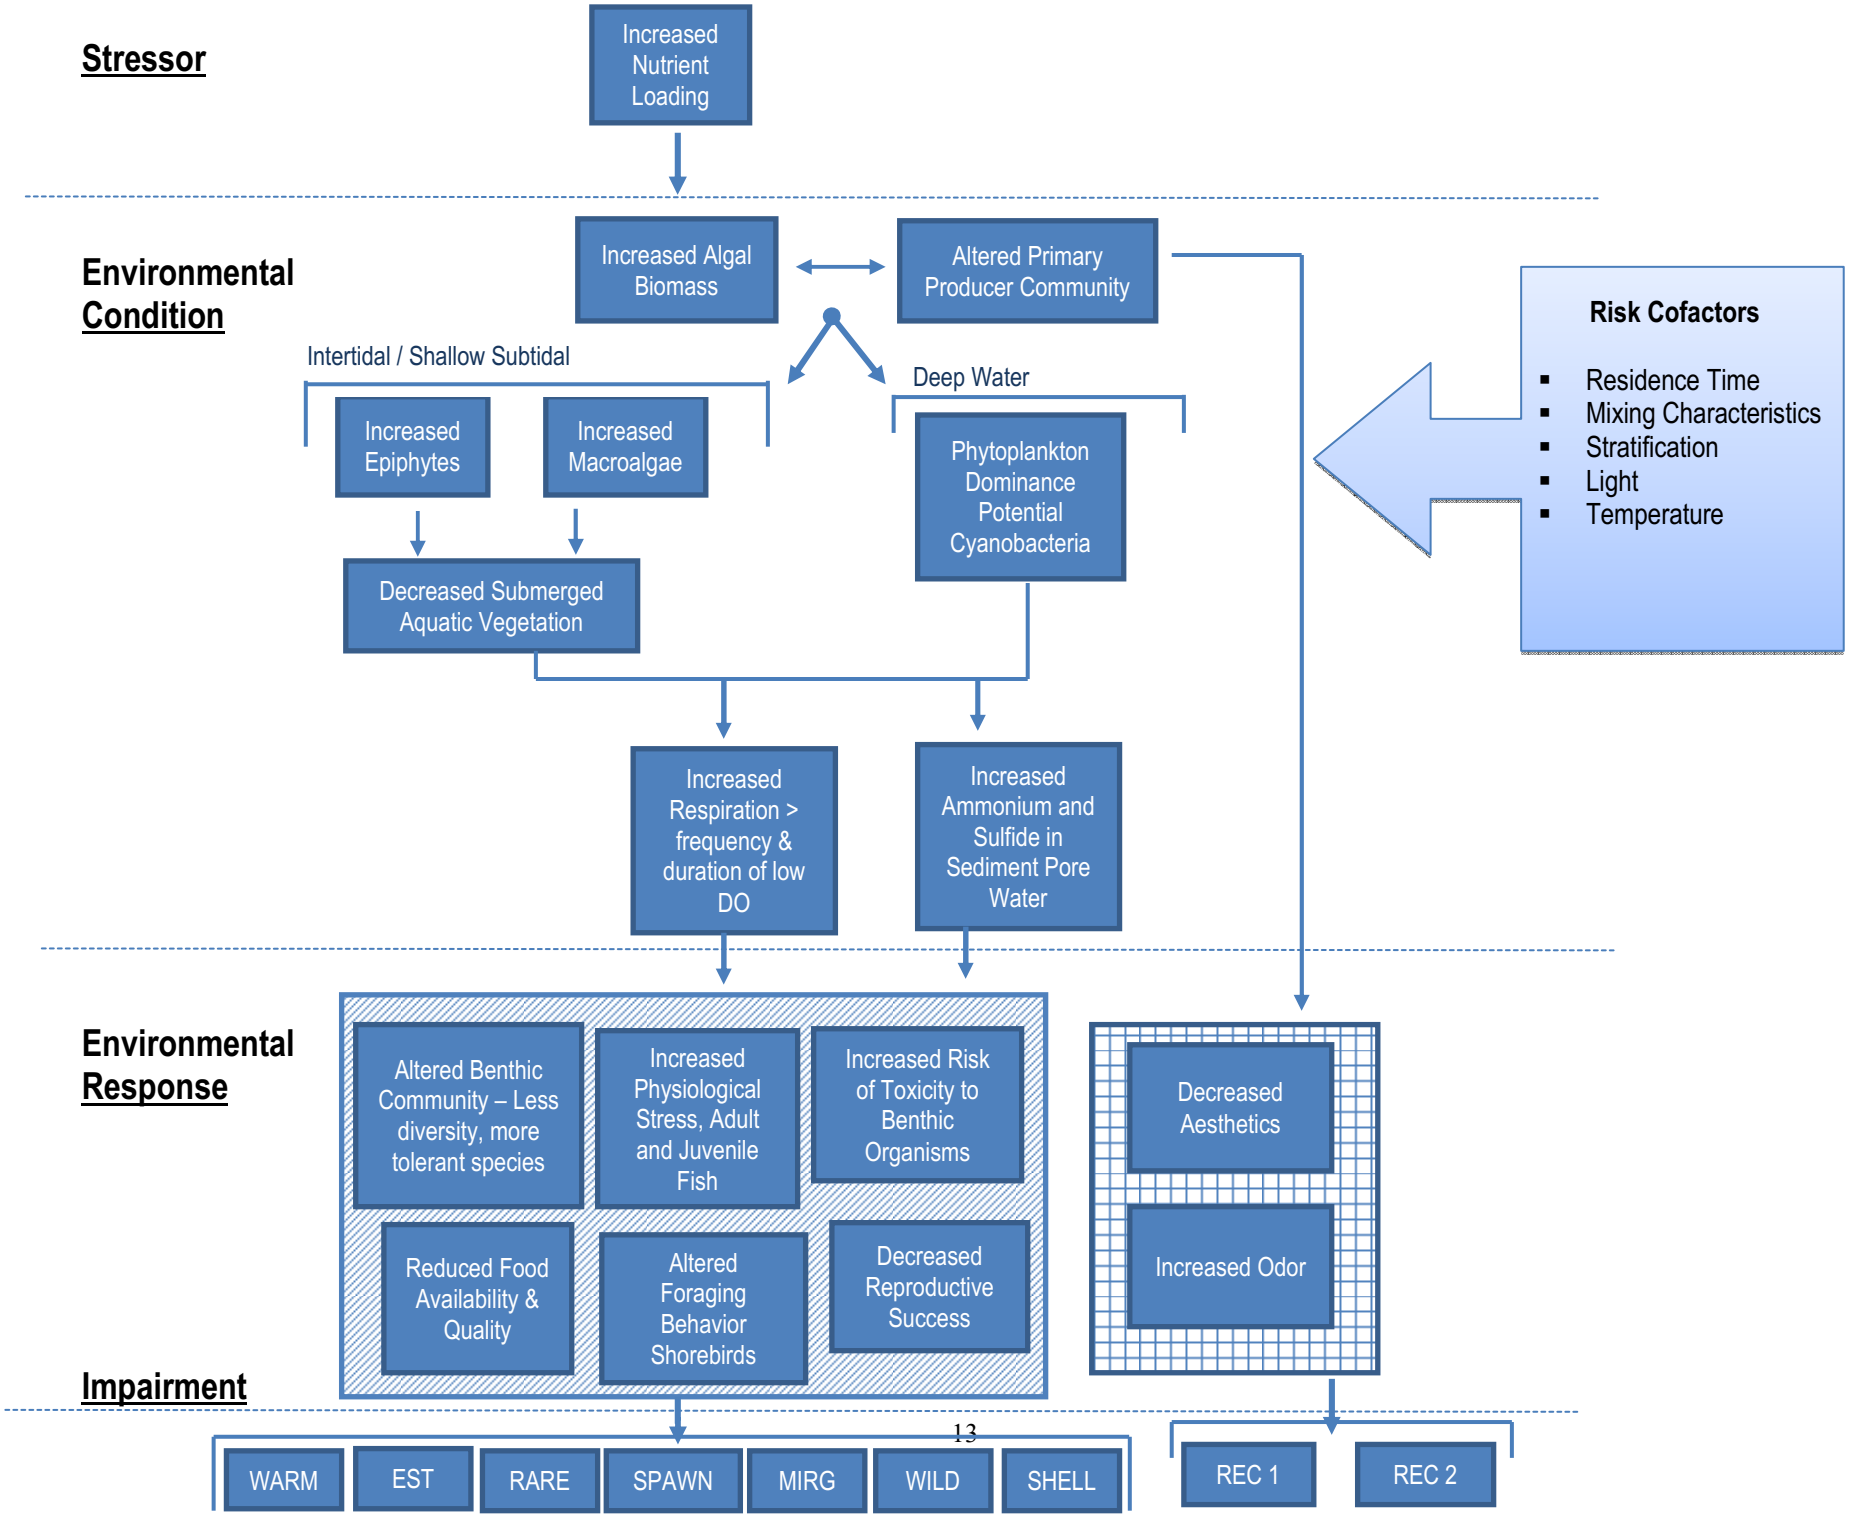

Figure 2-2 Conceptual Model for Estuaries

2.2 Water Quality Standards

California water quality standards consist of the following three elements: 1) beneficial uses, 2) narrative and/or numeric water quality objectives, and 3) an antidegradation policy. In California, beneficial uses are defined by the regional boards in their Water Quality Control Plans (Basin Plans). Narrative and numeric objectives are designed to be protective of the beneficial uses specified in the Los Angeles Region Basin Plan.

2.2.1 Beneficial Uses

The Basin Plan for the Los Angeles Regional Board (LARWQCB, 1994) defines twenty (20) beneficial uses for Ventura River and Ventura River Estuary (Table 2-1). These beneficial uses are recognized as existing (E), potential (P) or intermittent (I) uses. Nutrient loading and the resulting ecological responses in Ventura River and the estuary may result in impairments of beneficial uses associated with recreation (REC1 and REC2), aquatic life (WARM, COLD, EST, WILD, RARE, MIGR, SPWN, and WET), and water supply (MUN).

The most sensitive beneficial use in the Ventura River watershed is the cold water aquatic habitat (COLD) use and the associated migratory (MIGR) and spawning and early development (SPWN) uses. The Ventura River and its tributaries is home to the Southern California Steelhead, which was first recognized as endangered by the NOAA National Marine Fisheries Service (NMFS) in 1997. It status as endangered was reaffirmed in 2006. According to NMFS, the total population of the Southern California Steelhead has dropped from 32,000-46,000 spawning adults to less than 500 (NOAA 2012). The Ventura River, Ventura River Estuary, San Antonio Creek, Canada Larga, Matilija Creek and North Fork Matilija Creek among other tributaries have been designated by NMFS as critical habitat for the remaining population of the Southern California Steelhead.

The municipal and domestic supply (MUN) use designation applies to Ventura River Reaches 1 and 2, Canada Larga, and Matilija Creek as a potential (P) beneficial use. This beneficial use, for Ventura River and its tributaries, is indicated with an asterisk in the Basin Plan as a conditional use. Conditional designations are not recognized under federal law and are not water quality standards requiring TMDL development at this time. (See Letter from Alexis Strauss [US EPA] to Celeste Cantú [State Board], Feb. 15, 2002)

e – One or more rare species utilize all oceans, bays, estuaries, and coastal wetlands for foraging and/or nesting
f – Aquatic organisms utilize all bays, estuaries, lagoons, and coastal wetlands, to a certain extent, for spawning and early development. This may include migration into areas which are heavily influenced by freshwater inputs.
g – Condor refuge

2.2.2 Water Quality Objectives

The Basin Plan specifies narrative and numeric objectives, which both apply to Ventura River and Ventura River Estuary. The following narrative objectives apply to this TMDL.

> **Biostimulatory Substances:** *Waters shall not contain biostimulatory substances in concentrations that promote aquatic growth to the extent that such growth causes nuisance or adversely affects beneficial uses.*
>
> **Taste and Odor:** *Waters shall not contain taste or odor producing substances in concentrations that impart undesirable tastes or odors to fish flesh or other edible aquatic resources, cause nuisance, or adversely affect beneficial uses.*

The numeric water quality objects applicable to this TMDL are listed below.

> **Dissolved Oxygen (DO):** *At a minimum the mean annual DO concentrations of all waters shall be greater than 7.0 mg/L, and no single determinations shall be less than 5.0 mg/L except when natural conditions cause lesser concentrations.*
>
> *The dissolved oxygen content of all surface waters designated as both COLD and SPWN shall not be depressed below 7 mg/L as a result of waste discharges.*
>
> **pH:** *The pH of inland surface waters shall not be depressed below 6.5 or raised above 8.5 as a result of waste discharges. Ambient pH levels shall not be changed more than 0.5 units from natural conditions as a result of waste discharge.*
>
> *The pH of bays or estuaries shall not be depressed below 6.5 or raised above 8.5 as a result of waste discharges. Ambient pH levels shall not be changed more than 0.2 units from natural conditions as a result of waste discharge.*
>
> **Ammonia:** *In order to protect aquatic life, ammonia concentrations in inland freshwaters shall not exceed the values calculated for the appropriated in-stream conditions shown in tables 3-1 to 3-3 in the Basin Plan.*
>
> *For inland surface waters not characteristic of freshwater the four-day average concentration of un-ionized ammonia shall not exceed 0.035 mg/L and the one-hour average concentration shall not exceed 0.233 mg/L.*
>
> *Determination of Freshwater, Brackish Water or Saltwater Conditions*
> *For inland surface waters in which the salinity is equal to or less than 1 part per thousand 95% or more of the time, the applicable objectives are the freshwater objectives, based on the US EPA "1999 Update of Ambient Water Quality Criteria for Ammonia." (2) For waters in which the salinity is equal to or greater than 10 parts per thousand 95% or more of the time, the applicable objectives are a 4-day average concentration of 0.035 mg un-ionized NH3/L and a one-hour average concentration of 0.233 mg un-ionized NH3/L. (3) For waters in which the*

salinity is greater than 1 but less than 10 parts per thousand, the applicable objectives the more stringent of the freshwater or saltwater objectives.

Nitrogen: *Waters shall not exceed 10 mg/L nitrogen as nitrate-nitrogen plus nitrite-nitrogen (NO3-N + NO2 – N), 45 mg/L as nitrate (NO3), 10 mg/L as nitrate-nitrogen (NO3-N) or 1 mg/L as nitrite-nitrogen (NO2-N) or as otherwise designated in Table 3-8.*

Basin Plan Table 3-8 presents the nitrogen objective for Ventura River Reaches 5,4,3, and 2 as 5mg/L. This limit also applies to Cañada Larga and San Antonio Creek as tributaries to Reaches 2 and 4, respectively.

This nitrogen objective is established for the protection of the MUN beneficial use and objectives in Table 3-8 are waterbody specific. As presented in the problem identification and water quality assessment sections of this document, the numeric objective of 10 mg/L and the waterbody specific objective 5 mg/L is not sufficiently protective to control excessive algal growth and eutrophic conditions in the river and estuary and thus protect the most sensitive beneficial use in the watershed, which is aquatic life. Current nitrate loading in the watershed is a contributor to the exceedence of the biostimulatory substances narrative objective. Therefore, this TMDL will set numeric targets and allocations at levels necessary to attain the biostimulatory substances objective and protect all beneficial uses.

2.2.3 Antidegradation

State Board Resolution 68-16, “Statement of Policy with Respect to Maintaining High Quality Water” in California, known as the "Antidegradation Policy," protects surface and ground waters from degradation. Any actions that can adversely affect water quality in all surface and ground waters must be consistent with the maximum benefit to the people of the state, must not unreasonably affect present and anticipated beneficial use of such water, and must not result in water quality less than that prescribed in water quality plans and policies. Furthermore, any actions that can adversely affect surface waters are also subject to the federal Antidegradation Policy (40 CFR 131.12). The proposed TMDL will not degrade water quality, and will in fact improve water quality as it is designed to achieve compliance with existing water quality standards in order to ensure that beneficial uses of the Ventura River system are fully supported.

2.3 Water Quality Data Summary

This section presents a review of the data used by the Los Angeles Regional Board to identify reaches of the Ventura River and Estuary, San Antonio Creek, and Cañada Larga as impaired by algae, eutrophic conditions, nitrogen, and low dissolved oxygen. Additional data, where available, were also used to assess the current condition of the waterbodies.

2.3.1 Basis for 303(d) Listings

The basis for the algae and eutrophic condition impairments in Ventura River Reach 1 and 2 and the estuary was the 1996 Water Quality Assessment (WQA) conducted by Regional Board. There is limited information available regarding these listings; however, the information that is available is summarized below.

As part of the 1996 WQA, Regional Board staff conducted field surveys that included observations of algae during the summer season. The field logs used in this work included qualitative observations of algae. A standard field log worksheet, developed by Regional Board staff, was used to summarize observations made during sampling events. The worksheet directed staff to evaluate algal cover ranging from zero to dense (> 50% cover) and floating versus attached algae. The worksheet results were compiled and waterbodies were characterized as impaired or attaining beneficial uses.

San Antonio Creek is listed for nitrogen on the 2002 303(d) list. The fact sheet (2002 CWA 303(d) List Staff Report, 2003 page 4-198) presents the staff recommendation of listing this waterbody due to greater than 10% exceedances of the applicable nitrogen objectives of 5 mg/L. Similarly, Cañada Larga was identified as impaired and placed on the 2002 303(d) list for greater than 10% exceedances of the dissolved oxygen objective (2002 CWA 303(d) List Staff Report, 2003 page 4-78).

2.3.2 Assessment of Current Water Quality Data

Staff has evaluated data from various sources including those listed below.

- Regional Board funded contracts, University of California, Santa Barbara Study
- Ojai Valley Sanitation District receiving water monitoring
- Santa Barbara Channel Keeper (SBCK), Ventura Stream Team
- Ventura County Watershed Protection MS4 monitoring
- Southern California Stormwater Monitoring Coalition (SMC)
- Regional Board Surface Water Ambient Monitoring Program (SWAMP)

<u>Dissolved Oxygen</u>

The photosynthetic and respiration activities of algae can drive significant changes in DO concentrations over a 24-hour period. In fact, when algae are abundant they can act as the most significant influence on the magnitude of diurnal oscillations in dissolved oxygen concentrations (Wetzel, 2001). Considering algal respiration and photosynthesis separate from other factors (e.g. water turbulence, water depth, and temperature), nighttime respiration reduces dissolved oxygen until the daytime activity of photosynthesis reverses the process and produces oxygen. However, other physical factors including temperature, turbulence, and water depth also work to incorporate oxygen from the atmosphere into the water. These physical processes mediate declining nighttime oxygen concentrations.
The graph below (Figure 2-3) summarizes the pre-dawn dissolved oxygen measurement made by the SBCK during the growing season from 2008 through 2011. The pre-dawn measurements of dissolved oxygen are not the exact minimum oxygen concentration in the

river because of physical factors also influencing the amount of oxygen in the river. However, the pre-dawn measurements provide a very reasonable estimate of the minimum dissolved oxygen observed during a 24-hour period. Two noteworthy elements of this figure are that 1) sites in the upper watershed (Matilija above the dam and North Fork Matilija) express pre-dawn DO concentrations below the 7 mg/L water quality objective less frequently than sites in the middle and lower parts of the watershed and 2) all sites demonstrate interannual variability most likely related to the magnitude of algal growth and flow conditions.

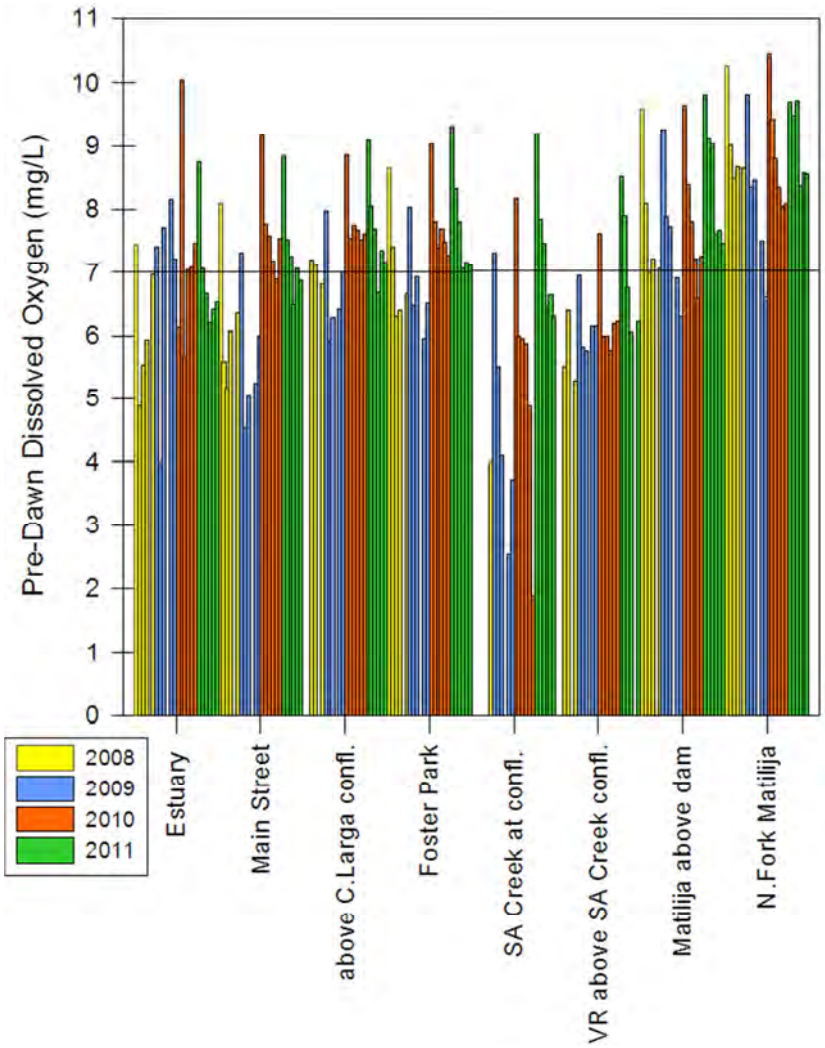

Figure 2-3 Pre-dawn dissolved oxygen measurements during the growing season, 2008 through 2011

Figures 2-4 – 2-10 present the difference between pre-dawn and afternoon DO measurements at strategic locations in the watershed. These figures show more clearly the influence of algal biomass on daily dissolved oxygen concentrations. The pre-dawn measurements represent the daily minimum concentration when nighttime respiration processes have reduced oxygen concentrations. The afternoon measurement captures the daily maximum concentration when photosynthesis leads to super saturated conditions.

The most dramatic oxygen depletion events occurred on San Antonio Creek in the late summer months (Figure 2-7). It is likely that low flow conditions contributed to the depleted oxygen condition. The minimum stream oxygen concentration is proportional to the amount of algal biomass present in the river – greater amount of algal biomass, the greater amount of oxygen removed during nighttime respiration. However, it is also inversely proportional to the amount of flow – a greater flow mitigates the impact of algal respiration on DO because it is more difficult and requires larger amounts of algae to effect large volumes of flowing water. The flow in San Antonio Creek at the confluence of Ventura River typically decreases to approximately 1 cfs by late summer (SBCK flow data).

A less extreme example was observed in the upper watershed at Matilija Creek (Figure 2-9); the lowest DO measurement was consistently observed in late summer when flows were at the lowest (~ 1 – 3 cfs). In contrast to the upper watershed and tributary areas, the lower watershed sites (Main Street and estuary) expressed low DO concentrations earlier in the summer aligned with maximum algal biomass growth. Extreme low flow conditions were prevented by discharge from the Ojai Valley WWTP (Figure 2-4 and 2-5).

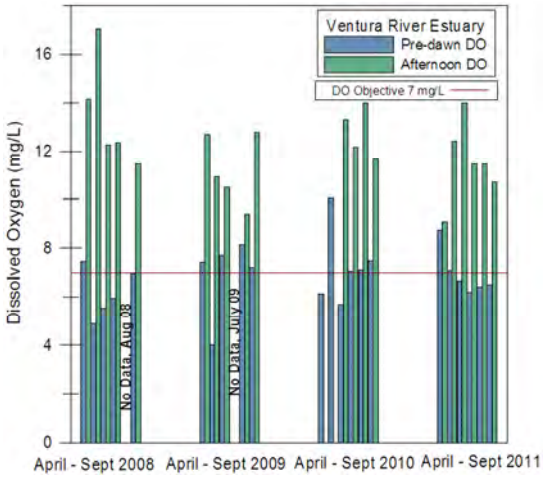

Figure 2-4 Estuary DO Measurements

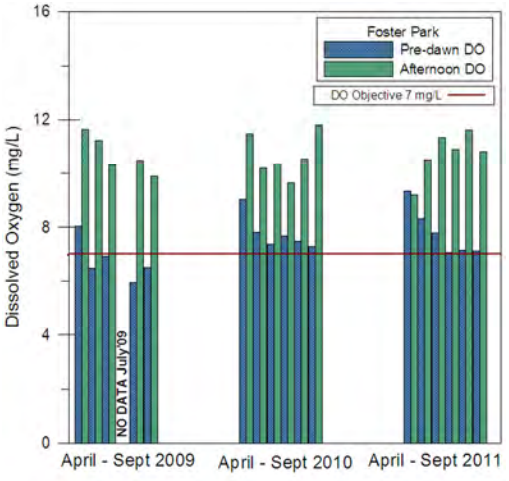

Figure 2-6 Foster Park DO Measurements

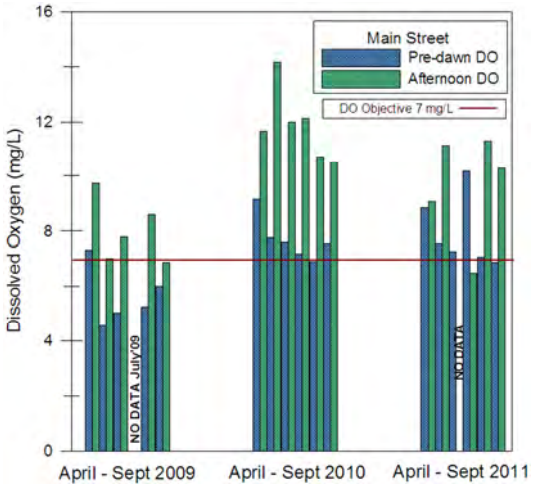

Figure 2-5 Main Street DO Measurements

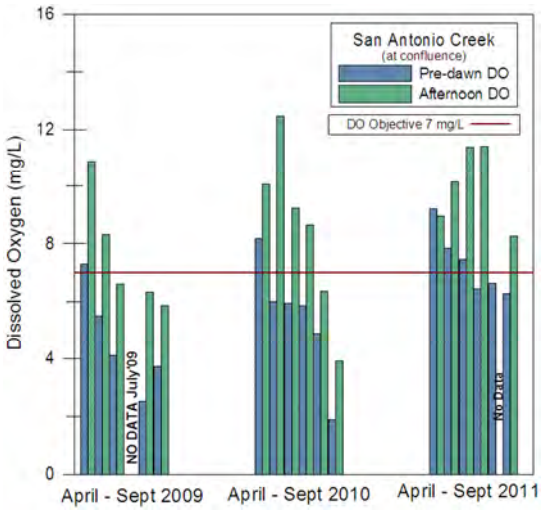

Figure 2-7 San Antonio Creek DO Measurements

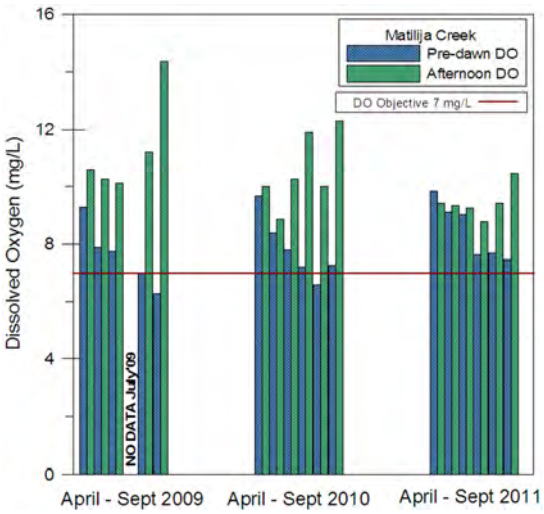

Figure 2-9 Matilija Creek DO Measurements

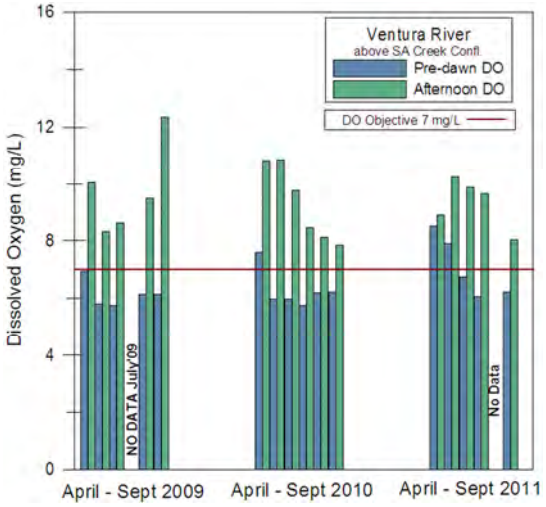

Figure 2-8 Ventura River above San Antonio Creek A Creek DO Measurements

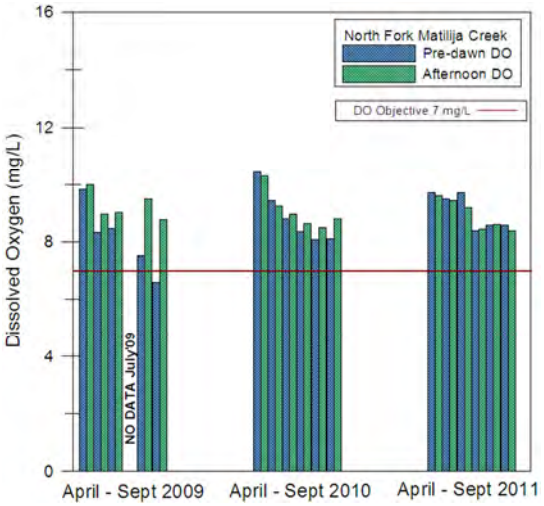

Figure 2-8 North Fork Matilija Creek DO Measurements

As can been seen from these graphs and the data in Appendix A, DO concentrations below the water quality objectives are repeatedly observed during the summer months. The SBCK pre-dawn DO data was assessed in accordance with the SWRCB *Policy for Developing California's Clean Water Act Section 303 (d) List* to evaluate potential DO impairments. The following stream locations were identified as impaired.

- Ventura River Estuary
- Ventura River at Main Street
- Ventura River above Cañada Larga confluence
- Ventura River at Foster Park
- Ventura River above San Antonio Creek confluence
- San Antonio Creek at confluence with Ventura River
- Lower San Antonio Creek
- Upper San Antonio Creek
- Pirie Creek (tributary to San Antonio Creek)

The DO objective of 7 mg/L was applied in this assessment to be protective of the COLD and SPWN beneficial uses. This objective was also applied to estuary because the estuary is designated with both SPWN and MIGR beneficial uses and endangered Southern California steelhead trout are present in this watershed.

Nutrients

The nutrient concentrations measured in-stream by SBCK demonstrate seasonal patterns with an expected amount of variability. Nitrogen, presented as nitrate - nitrogen in the figures below, generally peaks in the winter months as it is mobilized by winter storms and then begins to decline as it is taken up by algae and plants through the growing season. The sites Ventura River at Foster Park and Main Street (Figure 2-11 and 2-12) are a well-defined examples of this seasonal cycle; the variation in winter nitrogen peaks are related to the amount of rainfall in any given year and concentrations decline near zero during the prime growing season. A notable exception to this pattern is the increased nitrate concentration in San Antonio Creek in late spring and early summer 2001, 2005, and 2011. Based on the analysis presented in Nutrient Concentrations in the Ventura Watershed: 2008-2011 (Leydecker, March 2012), this nitrate increase is related to groundwater recharge with high nitrate waters in the upper San Antonio Creek drainage area.

Additionally, Ventura River at Shell Road and Ventura River above the Cañada Larga confluence exhibit a slightly different pattern. These sites are approximately 1.9 and 0.45 miles downstream of the Ojai Valley WWTP, respectively, and the in-stream nitrate concentrations reflect the continual nutrient inputs from the treatment plant. For example, seasonal peaks in concentration occur in late summer/early fall as discharge from the treatment plant increasingly dominates the flow in the river.

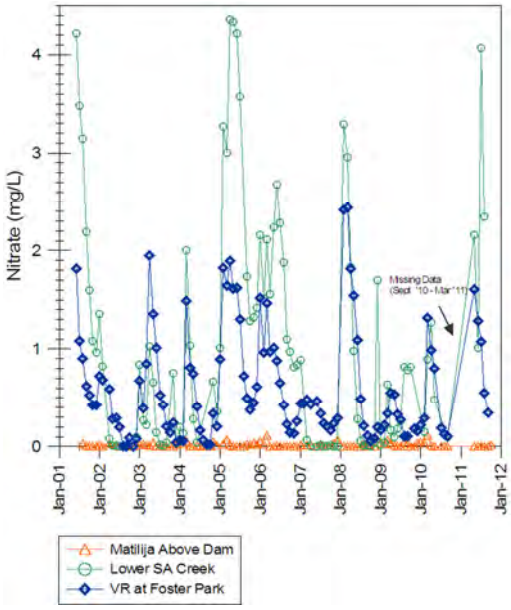

Figure 2-9 Nitrate Concentration Upper Watershed

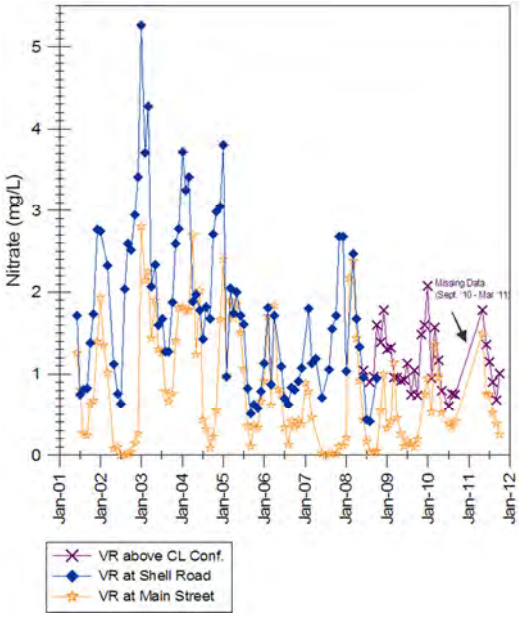

Figure 2-10 Nitrate Concentration lower watershed

Phosphate (dissolved) concentrations in the upper watershed (Matilija Creek) are generally measured as zero or nondetect with very slight increased concentrations (0.01 – 0.02) observed during the winter. The data from Ventura River at Foster Park show similar results albeit with slightly higher winter time increases (~0.01 – 0.03). Although, samples collected in November 2009 show a marked spike to approximately 0.1 mg/L phosphate. Phosphate concentrations measured below the treatment plant (Ventura River at Shell Road and above Cañada Larga confluence) exhibit increased dry season concentrations as the discharge accounts for the majority of flow. Phosphate measured at Main Street appears to follow the pattern of upstream measurements, but report slightly lower concentrations reflecting the biological uptake and processing between the sites.

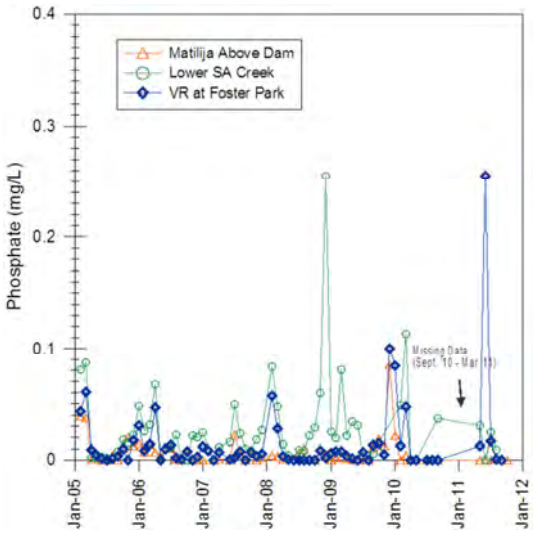

Figure 2-11 Phosphate Concentration Upper Watershed

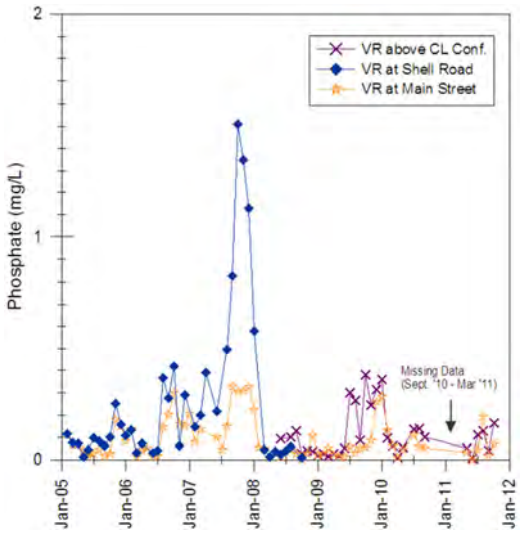

Figure 2-12 Phosphate Concentration Lower Watershed

As discussed above, in the late summer discharge from the WWTP dominates the flow in the lower portion of the watershed (Reaches 1 and 2). Thus, the in-stream nutrient concentrations largely reflect nutrients discharged from the plant. Over the years due to treatment upgrades and improved plant performance the amount of nitrogen discharged from the treatment plant has dramatically reduced. Figure 2-15, presents the effluent Total Inorganic Nitrogen (TIN) concentrations from treatment plant over time (Jan. 1979 – Dec 2011).

Through the mid-1990s, the plant operated with advanced secondary treatment including nitrification to oxidize ammonia, but not denitrification to reduce nitrate to nitrogen gas. Thus, the plant's discharge contained large amounts of nitrogen; the graph presents an average TIN effluent concentration of approximately 20 mg/L from the 1980s through the mid 1990s. In the summer of 1996 the Ojai Valley Sanitary District (OVSD) completed plant upgrades including denitrification and tertiary treatment, the result the improved treatment is clearly seen on the graph. The average effluent TIN concentration was reduced to 5 mg/L; a 75 percent reduction. Decreased in-stream nitrate concentrations also reflect improvements at the treatment plant (Figure 2-16). Prior to the upgrades in 1996 the average nitrate concentration approximately 1,000 yards downstream was 9.5 mg/L and after the upgrade the average in-stream concentration was 2.4 mg/L.

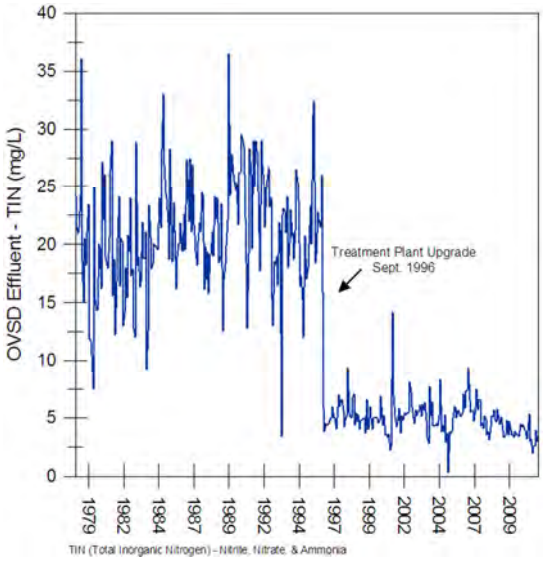

Figure 2-13 OVSD Effluent TIN Concentration 1979-2009

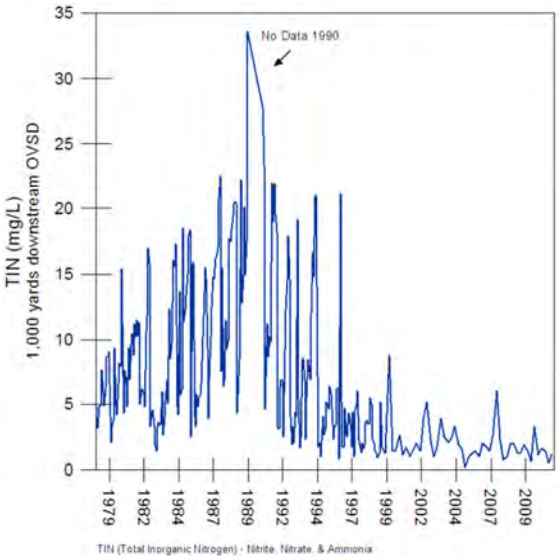

Figure 2-14 Ventura River TIN Concentration Downstream OVSD 1979-2009

Algal Biomass

Benthic and macroalgae (total algal biomass) can be found throughout the Ventura River watershed. In 2008 as part of a Regional Board contract the University of California, Santa Barbara measured algal biomass at targeted locations in the watershed. Sites were selected to provide a gradient of development and land use in the watershed. Each site was sampled twice, once in early summer (June 2008) and once in late summer (September 2008). Figure 2-17 below presents a watershed map and bar graphs of the total algal biomass

results. Algal biomass in the upper watershed was quite low over both months (<60 mg/m^2). In the middle portion of the watershed (approximately San Antonio Creek to Foster Park) there was a marked difference in biomass present in June versus September and concentrations were considerably greater as compared to the upper watershed sites. In June 2008 biomass measured in the middle watershed ranged from approximately 200 – 400 mg/m^2; by September biomass levels had declined and ranged from 90 – 150 mg/m^2. The highest algal biomass concentrations were reported in the lower watershed below the wastewater treatment plant. The maximum concentration was in the Ventura River at Main Street, 1037 mg/m^2 in June, and the minimum concentration observed (in the lower watershed) was 225 mg/m^2 at the Shell Road site in September 2008.

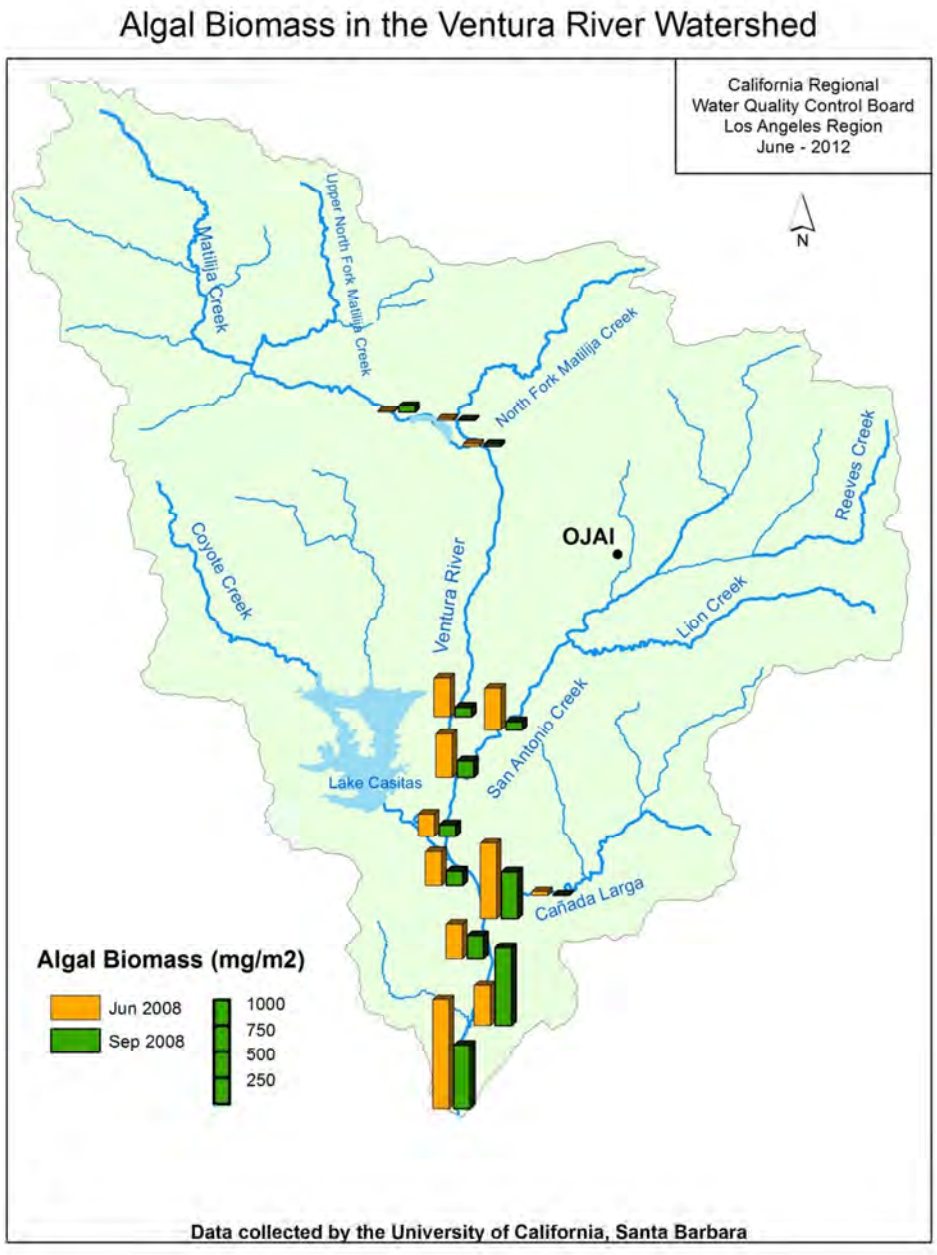

Figure 2-15 Algal Biomass Ventura River Watershed, 2008

In addition to the project conducted by UCSB, the Southern California Stormwater Monitoring Coalition (SMC) collected algal biomass data as part of the bioassessment monitoring required under the Ventura County MS4 permit. This monitoring program has a probabilistic design (i.e. random site selection and not the same sites every year) and only samples sites in spring to early summer because this timeframe coincides with the index period (spring to early summer) for benthic macroinvertebrates sampling. Since this algae data was collected as part of a larger monitoring program the results may not capture the seasonal maximum algal biomass. However, the results do provide useful information to assess conditions and investigate algal dynamics in the watershed.

Although there are results from multiple years presented on Figure 2-18 it is best to evaluate results from the same year at different locations because the interannual variation in algal biomass can be significant. In 2008 the SMC found small (<20.0 mg/m^2) amounts of algal biomass in Upper North Fork Matilija Creek and Ventura River Reach 4. In 2009 sites in North Fork Matilija and upper Reach 4 maintained low amounts of biomass; however, the site in San Antonio Creek had higher concentration (~ 50 mg/m^2) and lower Ventura River was found to be 112 mg/m^2. Matilija Creek and Ventura River near Foster Park had similar amounts of algal biomass as measured in 2010 and in 2011; the upper tributaries and San Antonio Creek had biomass concentrations from 25 – 100 mg/m^2. In summary, different amounts of algae grow in different watershed locations and different amounts of algae grow in different years.

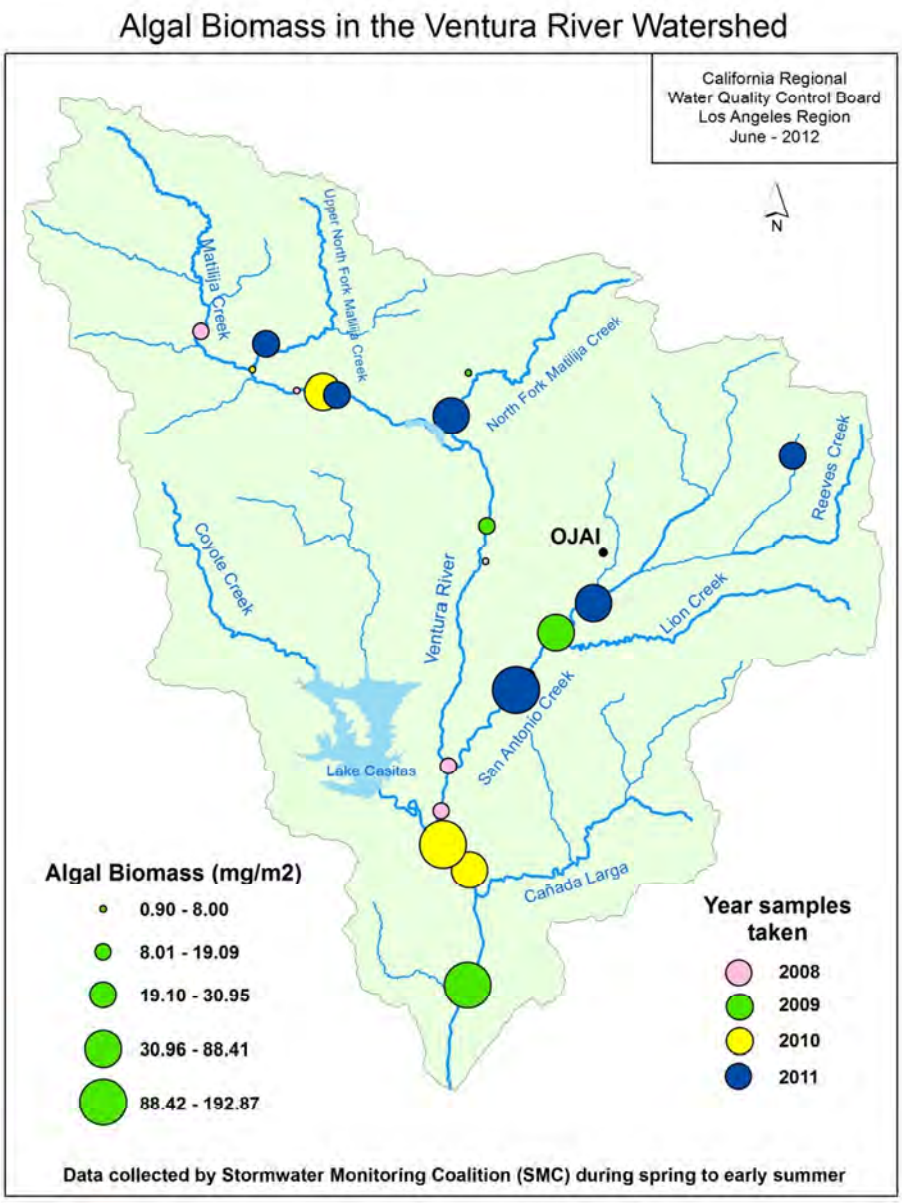

Figure 2-16 Algal Biomass Ventura River Watershed, 2008-2011

The interannual variation in algal biomass growth appears to be closely related to rainfall in the preceding year (Lydecker, 2003 and Lydecker et al., 2004). For example, large winter storms that scour the river removing plants, brush, and riparian cover change the river's physical habitat creating an open channel with available light and nutrients, which favors algae growth. The photographs below provide a dramatic example of the physical changes that can occur (photos provided by Al Lydecker). In 2004 the Ventura River at Main Street Bridge had a large amount of trees and plants established in the river channel and the open water portion of the channel was quite narrow. However, the very large winter storms of 2005 completely cleared the channel of vegetation and shifted the river's physical habitat to favor algal growth.

Figure 2-17 Main Street Bridge 2005

Overtime, during years with more typical rainfall or drought years the river channel is reclaimed by fast growing riparian trees (e.g. willows), shrubs, and various aquatic plants this once again narrows the channel, increases shading, and creates a habitat in which algae are less competitive. These changes can be observed moderately overtime, that is dramatic storm events are not the only observation of interannual variation on the river. The photos below document the succession of the channel from fairly open, favoring algal growth, to

being dominated by rooted aquatic plants (Ventura River at Main Street Bridge looking upstream) (photos from Al Lydecker, Watershed U handout 2010).

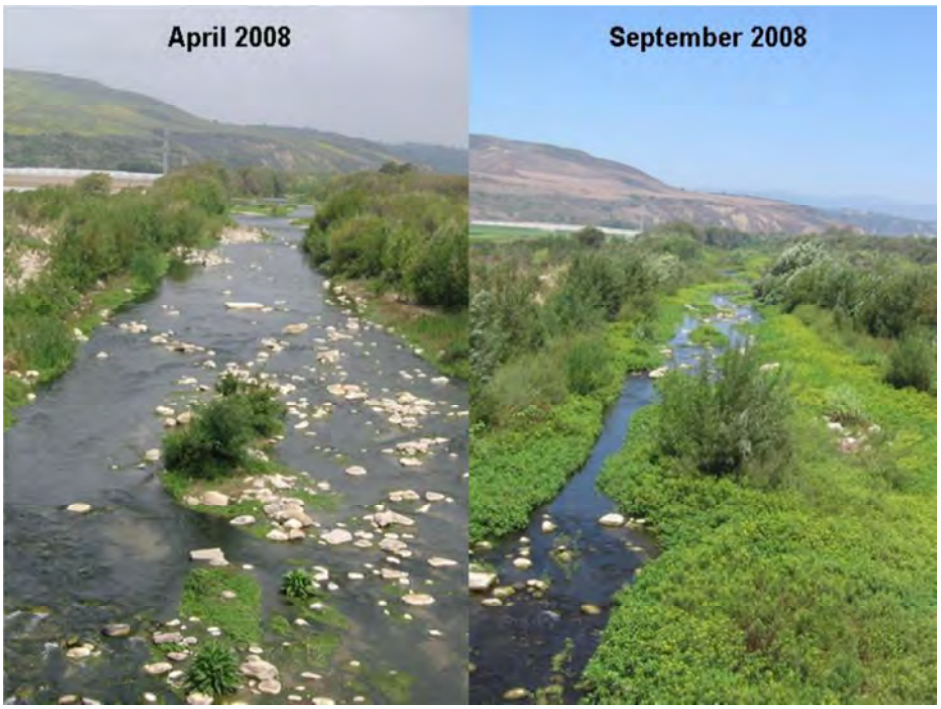

Figure 2-18 Main Street Bridge 2008

The interannual changes described above occur throughout the watershed; although not as dramatically as observed in the lower watershed. (Lydecker, 2010).

The physical changes that occur on the Ventura River due to the wet-winter dry-winter rainfall pattern impacts the ecology of the river and influences the amount algae observed from year to year (Lydecker, 2010). Because of the changing physical conditions and related cofactors it is important that the TMDL address nutrient loading to the river in addition to any watershed wide projects that may be designed to promote certain cofactors such as, increased riparian area and canopy cover.

Algal species composition is another line of evidence when evaluating stream nutrient conditions. Shifts in algal species composition can reflect changes in nutrient concentrations (US EPA, 2000b). The 2008 UCSB study evaluated algal species composition in the Ventura River Watershed (Figure 2-21). In the June sample set (Figure a) all sites were composed of *Cladophora* and diatoms; however, the upper watershed sites had considerably lower percentages of *Cladophora* and statistically significant higher amounts of diatoms (UCSB, 2009). By late summer (Figure b) diatoms and other marcoalgae genera had become more prominent that *Cladophora*. The summer time shifts in algal composition in the Ventura River have also been documented by the work of SBCK and regional expert Al Lydecker (Lydecker, 2008).

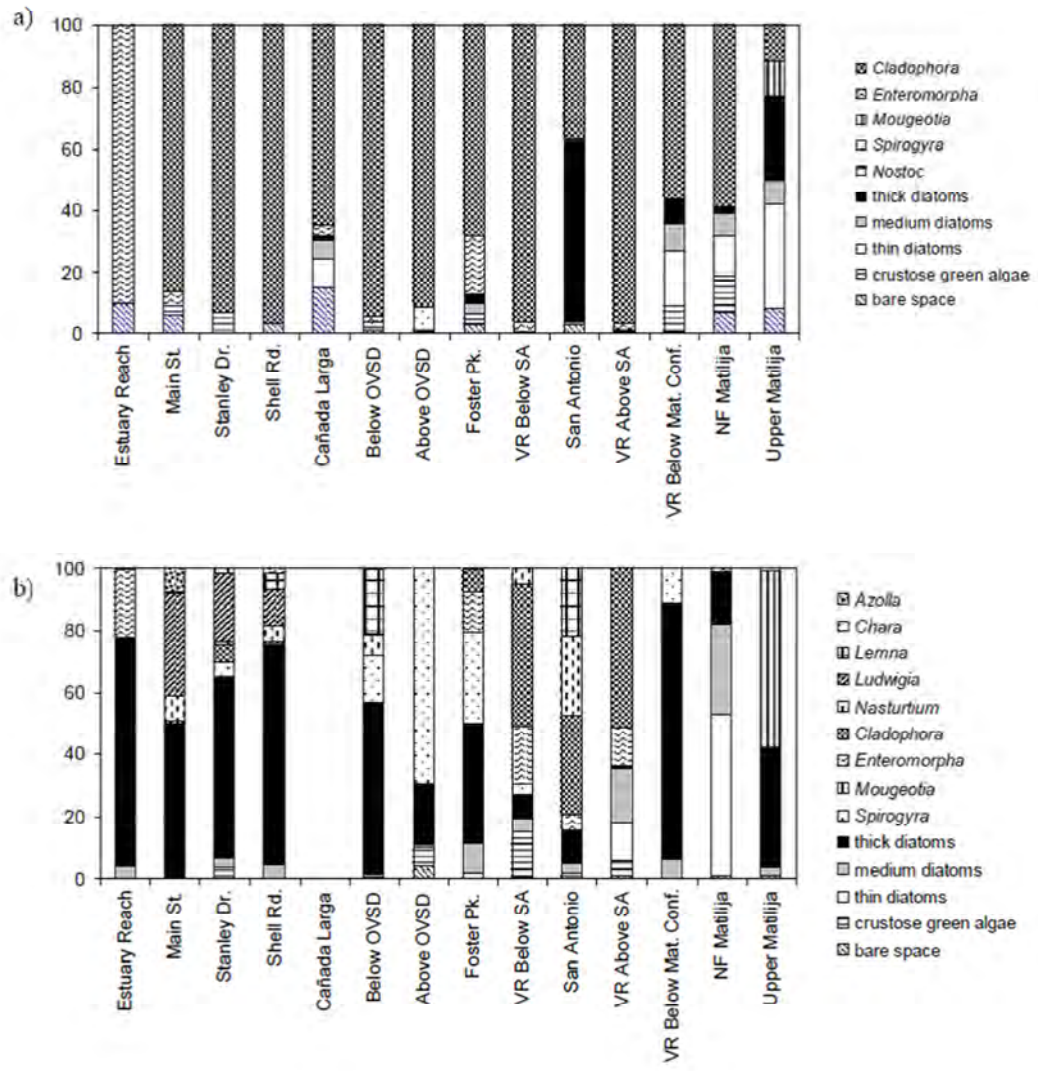

Figure 2-19 Percent Cover of Different Algal Types (UCSB, 2008)

2.4 Problem Statement

This data analysis demonstrates the water quality problems related to eutrophication and increased nutrient loading and documents the exceedance of the dissolved oxygen and biostimulatory substances water quality objectives during the dry season (May 1st to September 30th), when algae growth primarily occurs. The nutrient concentrations in the Ventura River and Estuary contribute to the excessive algal biomass growth, which in turn contributes to low DO conditions. The DO information presented documents repeated poor DO conditions during the dry season which contribute to multiple impacts on cold water fish, including decreased growth, increased stress, decreased reproductive success and increased juvenile and adult fish mortality. The changes in the river and estuary ecosystem

degrades cold water habitat leading to impaired aquatic life and recreation beneficial uses. This TMDL will address impairments causing the dry season (May 1st to September 30th) exceedance of the biostimulatory substances water quality objective in Ventura River, Estuary and tributaries (Table 2-2).

Table 2-2 Impairments addressed by this TMDL

Waterbody	Impairment
Ventura River Estuary	Algae, eutrophic conditions, and low DO
Ventura River Reach 1	Algae, low DO
Ventura River Reach 2	Algae, low DO
Cañada Larga	Low DO
Ventura River Reach 4	Low DO
San Antonio Creek	Nitrogen and low DO

While the nutrient concentrations present in the river during the winter months are sufficient to support algal growth, cofactors such as, flow and temperature exert greater influence on the river. Also, the typical seasonal succession of primary producers generally shifts in the winter to be dominated by aquatic plants (Al Lydecker, personal communication). The changes in cofactors and ecology minimize winter season algal growth. For example, the first significant rain event of the season will scour algae from the river and higher winter flows make it difficult for algae to recolonize. Additionally, cooler temperatures and reduced light further diminish winter season algal growth. The watershed nutrient wet-weather loads are generally delivered directly to the ocean and thus don't contribute to exceedance of the biostimulatory substances objective in the river or Estuary, which occurs during the dry season (May 1st to September 30th).

3. NUMERIC TARGETS

The section identifies numeric targets that can be used to assess attainment of water quality objectives and the protection of beneficial uses. Multiple numeric targets may be used when a single target is not sufficient to fully evaluate attainment of water quality standards and protect beneficial uses. For the pollutants addressed by this TMDL the numeric targets are expressed as algal biomass, macroalgal percent cover, phytoplankton biomass, dissolved oxygen, and pH (Table 3-1). The DO and pH numeric targets are set equal to the numeric water quality objectives contained in Chapter 3 of the Basin Plan and the numeric targets for algal and phytoplankton biomass and cover are established as a numeric interpretation the water quality condition that will demonstrate attainment of the water quality condition that will attain the narrative water quality objective for biostimulatory substances contained in Chapter 3 of the Basin Plan.

Table 3-1 TMDL Numeric Targets

Indicator	Numeric Target	Waterbody
Total Algal Biomass	150 mg/m^2 chlorophyll *a* as seasonal average	Ventura River and tributaries
Macroalgal Cover (attached & unattached)	$\leq$ 30 percent (seasonal average)	Ventura River and tributaries
Phytoplankton Biomass	20 µg/L chlorophyll *a* as seasonal average	Estuary (shallow subtidal area)
Macroalgal Cover	$\leq$ 15 percent (seasonal average)	Estuary (intertidal and shallow subtidal areas)
Dissolved Oxygen	$\geq$ 7 mg/L daily minimum	River, Tributaries and Estuary
pH	6.5 – 8.5 (instantaneous value)	River, Tributaries and Estuary
Biomass and percent cover indicator targets apply during the dry season when algae growth promarily occurs. The seasonal averaging period for algal biomass and percent cover is the dry season of May 1 to September 30. River indicators are averaged over a sampling reach as required by the SWAMP monitoring protocol Bioassessment SOP 02. Estuary macroalgal cover is measured using 3 transects and evaluating percent cover at 10 random points along each transect. Results are reported as a transect average. See methods used in the Bight '08 Estuarine Eutrophication Assessment (McLaughlin K et. al. Southern California Bight 2008 Regional Monitoring Program: Estuarine Eutrophication Assessment. Southern California Coastal Water Research Project. Costa Mesa, CA.		

The approach for setting the total algal biomass numeric target and establishing the TMDL is based on the California Nutrient Numeric Endpoints (NNE) framework (Tetra Tech 2006). The CA NNE, developed by USEPA Region 9 and the State and Regional Water Quality Control Boards, is a science-based approach to translate the narrative water quality objective for *Biostimulatory Substances* to numeric endpoints that can be applied in a TMDL or other regulatory program. The approach works to establish nutrient numeric endpoints based on an evaluation of site-specific risk to beneficial uses. The objective of the CA NNE is to control excess nutrient loads/concentrations to levels such that the risk or probability of impairing the beneficial uses is limited to an acceptably low level.

The NNE framework establishes a suite of biologically-based numeric thresholds (e.g. algal biomass) and links these thresholds to numeric nutrient endpoints (i.e. nutrient concentrations or loads) to address eutrophication. The linkage between the biological thresholds and numeric nutrient endpoints relies upon established load response relationships among nutrients, risk cofactors and biological response indicators and water quality models. The water quality models allow the derivation of site-specific nutrient allocations on the basis of site-specific conditions (i.e. most sensitive beneficial use, local characteristics of risk cofactors). This is presented in Sections 5 and 6, Linkage Analysis and Allocations.

The CA NNE is a scientifically sound approach because, except in extreme cases, increased nutrient concentrations do not directly impair beneficial uses. Rather, they cause indirect impacts by affecting biological response indicators like algal growth and low dissolved oxygen, which do directly impair beneficial uses (see conceptual models in Section 2). The indicators set as TMDL numeric targets provide a more direct measurement of beneficial use condition and whether beneficial uses are being fully supported in the waterbody. Additionally, the NNE framework provides multiple indicators (multiple TMDL numeric targets) in a weight of evidence approach, which provides a more robust means to assess beneficial uses.

For the total algal biomass indicator there is not definitive scientific consensus on the threshold that results in beneficial use impairment. This is because site-specific factors often play a significant role in determining the biological response to nutrient loading. To address this issue and provide for site-specific considerations the CA NNE includes a range of threshold values for biological indicators as presented in three Beneficial Use Risk Categories (BURC) (Tetra Tech, 2006). The categories are described below.

- BURC I: beneficial uses are attained and achieves narrative objective
- BURC II: may require an impairment assessment and site-specific nutrient endpoints
- BURC III: beneficial uses impaired and exceeds narrative objective

The BURC I/II boundary is the threshold below which there is general consensus that nutrients will not present a significant risk of beneficial use impairment. The BURC II/III boundary represents a value that is sufficiently high that there is consensus that the risk of beneficial use impairment by nutrients is likely above that threshold. Within BURC II, additional water body-specific cofactors should be considered as part of the analysis to determine an appropriate target.

Table 3-2 CA NNE Beneficial Use Risk Categories

Response Indicator	Risk – Category Boundary	Beneficial Use						
		COLD	WARM	REC 1	REC2	MUN	SPWN	MIGR
Benthic Algal Biomass in streams (mg chl-a/m2) -Maximum	I / II	100	150	C	C	100	100	B
	II / III	150	200	C	C	150	150	B
B – additional research is need to quantify linkage C – addressed by aquatic life criteria								

Regional Board staff used various lines of evidence to develop a numeric target for this TMDL. The California Nutrient Numeric Endpoints sets a benthic algal biomass target for the boundary between Beneficial Use Risk Category II and III for streams with a cold water aquatic habitat use (COLD) at 150 mg chlorophyll-a/m2, interpreted as a maximum biomass in time averaged over a reach (i.e., it does not apply to single point measurements). The NNE boundary target is based on a review of both regional and international studies. The US EPA compiled results of research and expert recommendations and found general agreement that algal biomass greater than 150 mg/m2 indicates nuisance conditions and water quality degradation in streams (US EPA, 2000b). This value is expected to protect the aquatic life and recreation beneficial uses.

The CA NNE provides for the evaluation of other lines of evidence to ensure the applicability of the boundary condition. Regional Board staff considered the 2008 diurnal oxygen impacts on reaches of the Ventura River where high amounts benthic algal biomass were observed and the well-established fact that the frequent low DO conditions present stressful conditions for resident (adult and juvenile) and migrating fish. An algal biomass target of 150 mg/m2 is expected to minimize the risk of low DO events in the river and fully protect the aquatic life beneficial use (Welch and Jacoby, 2004).

The other biological indicators (macroalgal cover and phytoplankton biomass) are established as additional measures to track the symptoms of eutrophication and water quality improvements. These targets are based on the review of available data and scientific literature. The numeric target for attached and unattached macroalgal percent cover in the river is $\leq$ 30 percent. This value is based on recommendations from Biggs (2000); the guidelines presented in this document were developed to help protect streams from excessive nutrient loading.

The estuary phytoplankton biomass target of 20 µg/L is based on the Assessment of Estuarine Trophic Status (ASSETS), developed by the National Oceanic Atmospheric Administration (NOAA) National Estuarine Eutrophication Assessment (NEAA) (Bricker, 2003). The eutrophication indicators in the ASSETS framework were set to ensure accurate characterization of water quality conditions and the response ranges were selected to categorize and rank estuaries based on water quality ranges. Chlorophyll *a* is used a primary indicator for eutrophic condition. The values within the condition ranges were developed from data across the US and discussions with regional experts. The target of 20 µg/L is the maximum value within the medium condition water quality range.

For the macroalgal percent cover numeric target in the estuary, staff relied upon the classification framework presented in Scanlan (2007). The percent cover boundaries were set based on information from the UK Department of the Environment, Transport and the Regions 2001 expert workshop. The Scanlan study was not specific to estuaries in Mediterranean climates; however, a study conducted in coastal lagoons in Italy (Bona, 2006) corroborates the thresholds in Scanlan (2007) and demonstrates that these thresholds are reasonable for Mediterranean climates. The numeric target for percent cover algal biomass is set at $\leq$ 15 percent; this target equates to good water quality at moderate amounts of biomass. Both of these estuarine water quality assessment frameworks

(ASSETS and Scanlan) were also used by the Southern California Bight 2008 Regional Monitoring Program coordinated by the Southern California Coastal Water Research Project (SCCWRP) to evaluate estuarine eutrophication.

The numeric target for dissolved oxygen of 7 mg/L is set equal to the Basin Plan objective for all waters in the Ventura River Watershed designated COLD and SPWN. This target is also applied to the estuary, which is designated SPWN and MIGR because this watershed supports a Southern California steelhead trout cold water fishery.

Other Regional Boards in California have adopted algae and nutrient TMDLs for streams and estuaries which relied upon narrative water quality objectives and scientific literature and/or the CA NNE to translate the objective into TMDL numeric targets and allocations. Table 3-3 lists Regions and TMDLs in which this was done and the response indicator targets.

Table 3-3 Stream Nutrient TMDLs in Other Regions Where the Biostimulatory Substances Narrative Water Quality Objective were Applied

Region	TMDL		Indicator		
			Algal Biomass (mg/m^2)	Percent Cover	DO (mg/L)
1	Klamath River (2010)		150 (growing season average)	none	Reach specific monthly minimum 85 % saturation (winter) 90 % saturation (summer)
3	Chorro Creek (2006)		150*	algal cover ≤ 40%	≥ 7 (daily minimum)
4	Malibu Creek (2003)	Creek	150	algal cover ≤ 30% for floating algae and ≤ 60% for bottom algae	≥ 7 (daily average)
		Lagoon	150	algal cover ≤ 30% for floating algae and ≤ 60% for bottom algae	≥ 7 (daily average)

*The TMDL discusses the threshold of 150 mg/m^2 algal biomass as a level that represents nuisance conditions; however, it was not assigned as a TMDL numeric target.

4. SOURCE ASSESSMENT

This section identifies the potential sources of nutrients in the Ventura River watershed. In the context of TMDLs, pollutant sources are classified as either point sources or nonpoint sources. Nonpoint sources originate from land runoff, precipitation, atmospheric deposition, drainage, seepage or hydrologic modification. The term "nonpoint source" is defined to mean any source of water pollution that does not meet the legal definition of "point source" in section 502(14) of the Clean Water Act. A point source as defined in the Clean Water Act means any discernible, confined and discrete conveyance, including but not limited to any pipe, ditch, channel, tunnel, conduit, well, discrete fissure, container, rolling stock, concentrated animal feeding operation, or vessel or other floating craft, from which pollutants are or may be discharged. Point sources as defined in the Clean Water Act include discharges from wastewater treatment plants and industrial and municipal storm drain outfalls, but do not include agricultural storm water discharges and return flows from irrigated agriculture.

The data review in this section focuses on identifying potential sources and providing nutrient loading estimates using available methods and data. The major categories of nutrient sources in the Ventura River watershed are:

Point Sources

- Stormwater and dry weather runoff from storm drains
- Ojai Valley WWTP discharge

Nonpoint Sources

- Runoff from horse and cattle facilities
- Runoff from agricultural areas
- Runoff from undeveloped natural areas
- Onsite wastewater treatment systems (i.e., septic tanks)
- Groundwater discharge
- Atmospheric deposition

For the purposes of the source assessment, the Ventura River watershed was divided into seven subwatersheds based on a GIS layer from VCWPD (Figure 4-1). These subwatersheds are the Upper Watershed, Ventura River Reach 4, Ventura River Reach 3, the Lower Watershed, San Antonio Creek, Cañada Larga, and Other (Coyote Creek above Casitas Dam).

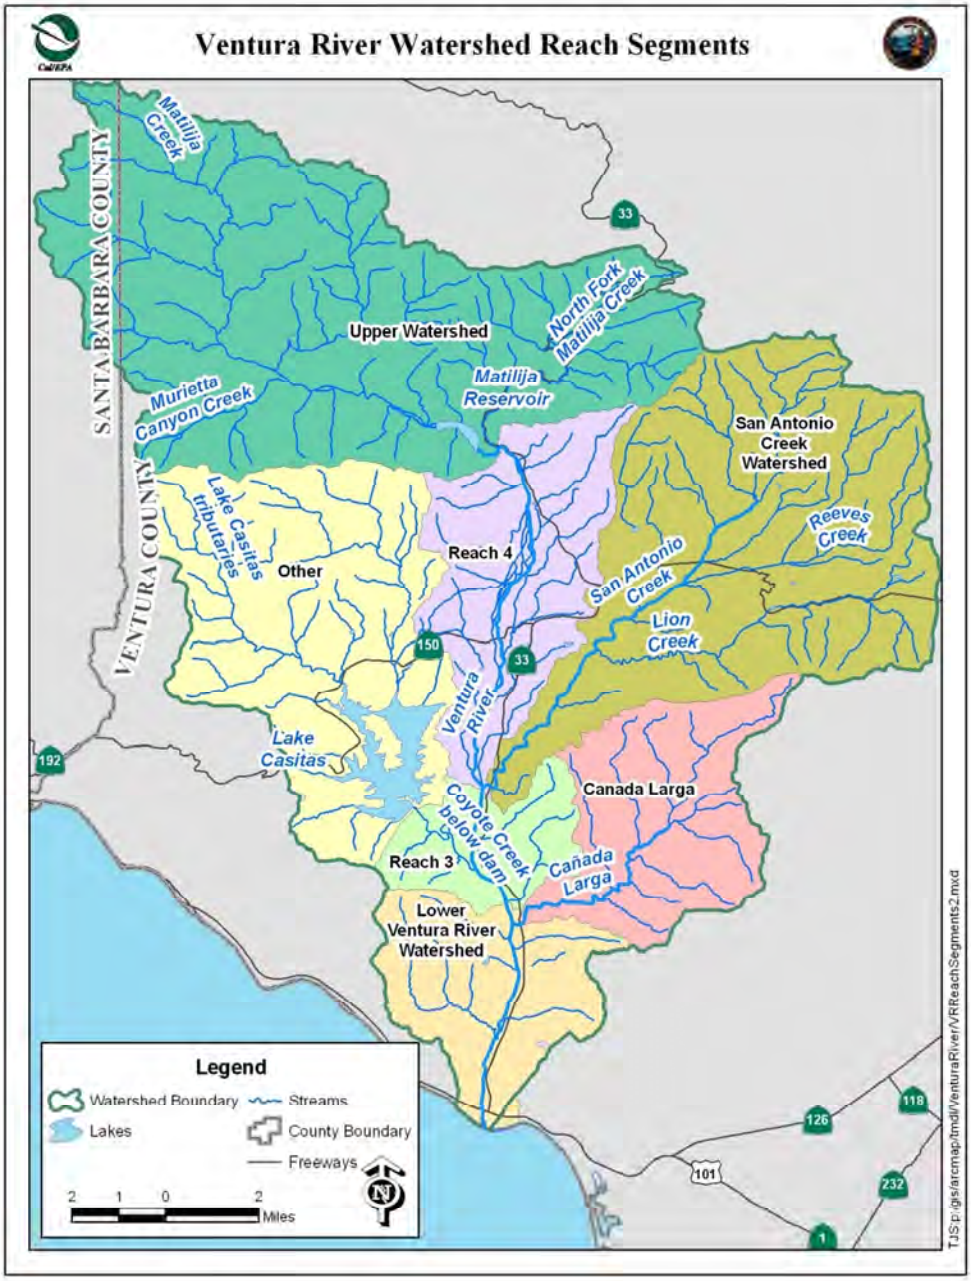

Figure 4-1 Ventura River Subwatershed

Most water in Lake Casitas goes to consumptive uses or evaporation and is rarely released below the dam (Tetra Tech, 2012). According to Casitas Municipal Water District staff, water is only released from the dam when it overflows. While there are valves at the base of the dam which can be opened in anticipation of high flows, those valves have never been opened and bottom waters are not discharged. The dam was built in 1958 and did not fill until 1978, when it spilled over. The last time water spilled over the Dam was in 1998 (an El Niño year). Thus, water is only released from the dam during very high flows and is released from the top of the reservoir. Therefore, the subwatershed draining to Lake

Casitas is not considered a potential source of nutrients to the Ventura River for the purposes of this source assessment. Land that drains to Coyote Creek downstream of the dam is considered a source and is included in this source assessment as part of the Reach 3 subwatershed.

Land use data (Table 4-1) were obtained from Southern California Association of Governments (SCAG, 2005). The 2005 dataset was used because the 2008 SCAG dataset is based on parcels and can leave out roads, which are considered in this source assessment. In addition, it should be noted that the total area for the 2005 SCAG land use data does not match the total area of the watershed based on the watershed delineation in the GIS maps provided by VCWPD. However, the discrepancy in area is due to differences in the area of open space, which has a negligible effect on the source assessment. The land uses in Table 4-1 were aggregated into 17 categories corresponding to high density residential, low density residential, commercial, industrial, public facilities, education, transportation, mixed urban, open, water, recreation, cropland/improved pasture, orchards/vineyards, nurseries, dairy/intensive livestock, other agriculture, and horse ranches land uses. The acreages of various land uses were further grouped based on similar nutrient loading patterns for the purposes of this source assessment.

Table 4-1 Drainage Areas (acres) for Various Land Uses in the Ventura River Watershed

Land Use	Upper Water-shed	Reach 4	Reach 3	Lower Water-shed	San Antonio Creek	Cañada Larga	Coyote Creek	Total for Water-shed
High Density Residential	0	1256	28.8	611	680	33.2	0	2610
Low Density Residential	110	1548	154	20.9	2160	33.3	24.4	4051
Commercial	0	83	0	207	153	1.69	0	445
Industrial	12.6	6.53	25.3	2766	163	5.08	0	2978
Public Facilities	0	97.1	275	53.6	80.7	127	112	746
Education	0	99.3	0.05	52.9	227	0.04	0	379
Transportation	0	7.58	44.3	185	6.38	8.40	0	251
Mixed Urban	0	0	0	6.30	7.62	0	0	13.92
Open	40,838	8990	4865	5950	24,829	11,721	21,827	119,018
Water	30.1	10.99	0	6.56	25.52	0	2596	2669
Recreation	34.4	45.0	28.7	84.1	408	0	134	735

Orchards/ Vineyards	3.41	1027	101	214	3009	21.9	25.5	4401
Nurseries	0	0	0	4.33	12.3	0	0	16.7
Dairy/Intensive Livestock	0	3.93	0	0	0	0	0	3.93
Other Agriculture	4.93	19.7	5.98	12.7	82.0	7.65	9.21	142
Horse Ranches	9.41	107	9.12	0	207	18.8	5.53	357
Total for all land uses	41,043	13,787	5709	10,307	32,745	12,312	24,734	140,638

4.1 Point Sources

The NPDES permits for stormwater and dry weather urban runoff discharges in the Ventura River watershed are the Ventura County municipal separate storm sewer system (MS4) permit (R4-2010-0108), the statewide California Department of Transportation (Caltrans) MS4 permit (99-06-DWQ), the statewide general industrial stormwater permit (97-03-DWQ), and the statewide general construction stormwater permit (2009-0009-DWQ).

The NPDES permits for wastewater and industrial discharges in the Ventura River watershed are for the Ojai Valley WWTP (R4-2008-0039) and four general NPDES permits for Foster Park Well Field (R4-2003-0108), Development and Startup Project Well

#2 Aquifer Testing (R4-2003-0108), San Antonio Filter Plant (R4-2009-0047), and Golden State Water Company Ojai-Mutual Plant (R4-2003-0108) (Table 4-2).

Table 4-2 Summary of NPDES Permits in the Ventura River Watershed

Type of NPDES Permit	Total Permits
Ventura County MS4	1
Caltrans MS4	1
General Industrial Stormwater	28
General Construction Stormwater	14
Ojai Valley WWTP (Major)	1
General NPDES Permits	4
Total	50

This source assessment quantifies the point source loadings from stormwater and dry weather urban runoff sources and the Ojai Valley WWTP. The loadings from the general NPDES permits are not quantified in this source assessment. General Permit No. R4-2003-0108 is for discharges of groundwater from potable water supply wells to surface waters, including groundwater generated during well purging for data collection purposes, extracted from major well-rehabilitation and redevelopment activities, and generated from well drilling, construction, and development. General Permit No. R4-2009-0047 is issued to the San Antonio Filter Plant for the discharge of filter backwash water, redevelopment and start-up wastewater to San Antonio Creek. The discharges from the general NPDES permits are intermittent and considered negligible for the purposes of this source assessment.

4.1.1 Nutrient Loading from Stormwater and Dry Weather Urban Runoff Sources

Runoff from residential, industrial, commercial, and transportation areas is a significant source of nutrients to the Ventura River. The potential sources of nutrients from urban areas include fertilizer used for lawns and landscaping; organic debris from gardens, landscaping, and parks; trash such as food wastes; and domestic waste. Potential sources of nutrients from highways and transportation land uses include fallen leaves and other vegetation, vehicle exhaust, and atmospheric deposition. Nutrients build up, particularly on impervious surfaces, and are discharged into the receiving waters through storm drains when it rains or by dry weather runoff.

4.1.1.1 Wet-weather loading from Stormwater Sources

A Simple Method developed by Schueler (1987) was applied to estimate nutrient loads from urban stormwater runoff on annual basis to the Ventura River and its tributaries. This

method was based on a relationship between rainfall and stormwater runoff volume with an associated nutrient concentration.

Load (L) = P×Pj×R×C×A×0.226 **Equation (1)**

Where:
L: Annual wet-weather pollutant load (lb/year)
P: Annual rainfall depth (inches/year)
Pj: Factor that corrects P for storms that produce no runoff, use Pj = 0.9
R: Runoff coefficient for land use type (unitless)
C: Pollutant concentration in runoff (mg/L)
A: Drainage area (acres)
0.226 = unit conversion factor (L-lb/acre-inch-mg)

The annual rainfall data (Table 4-3) over a 20-water year period from 1987 through 2007 was obtained from "Data Summary Report – Ventura River Watershed Hydrology Model" prepared by Tetra Tech (2008). The average rainfall value for a rain gauge in each subwatershed was assigned to that subwatershed and used to estimate stormwater runoff volumes.

Table 4-3 Summary of annual rainfall data in the Ventura River Watershed from 1987 through 2007 (Tetra Tech, 2008)

Subwatershed	Rain Gauge Station	Average Annual Rainfall (inches/year)
Upper Watershed	Matilija Canyon (D207)	36.0
Reach 4	Meiners Oaks – County Fire Station	23.9
Reach 3	Ventura – Kingston Reservoir	20.7
Lower Watershed	Ventura – Downtown (Courthouse)	16.9
San Antonio Creek	Ojai – County Fire Station	22.3
Cañada Larga	Oak View - County Fire Station	22.9

In order to calculate nutrient loading from stormwater runoff, the following land use categories, based on Table 4-1, were assumed:

- Residential = High Density Residential + Low Density Residential
- Other Urban = Public Facilities + Education + Mixed Urban
- Commercial = Commercial
- Industrial = Industrial
- Transportation = Transportation

Runoff coefficients for several land uses (Table 4-4) were based on values reported by Ackerman and Schiff (2003). Staff compared the runoff coefficients from Ackerman and Schiff with runoff coefficients calculated by Larry Walker and Associates using the 2006 VCWPD Hydrology Manual (LWA, 2011). The runoff coefficients calculated by LWA were derived assuming a certain percent impervious land cover for each land use type. The runoff coefficient is also a function of soil type and rainfall intensity, but using land use and percent imperviousness to provide a rough estimate of runoff coefficients is appropriate. The runoff coefficients reported by Ackerman and Schiff and those calculated by LWA are very similar and make little difference in the calculation of loadings. This source assessment uses the Ackerman and Schiff runoff coefficients for residential, commercial, industrial, other urban, and transportation land uses. The residential runoff coefficient was used to calculate loading from both high density and low density residential land uses. A runoff coefficient of 0.9 was applied to the transportation land use in the Ventura River watershed because of the high percentage of impervious surfaces associated with this land use.

Table 4-4 Runoff coefficients for various land uses

Land Use	Runoff Coefficient
Residential	0.39
Other Urban	0.41
Commercial	0.61
Industrial	0.64
Transportation	0.9

The concentration of nutrients in stormwater runoff (Table 4-5) were obtained from stormwater event mean concentrations (EMCs) monitored by VCWPD from residential, commercial, and industrial land use sites throughout Ventura County (VCSQMD, 2001) and from outfall monitoring sites within the Ventura River watershed at Meiners Oaks and Ojai from 2010 and 2011 for the other urban land use category. EMCs represent the concentration of a pollutant contained in stormwater runoff over the length of a storm event. The EMCs of total nitrogen and total phosphorus measured from Caltrans statewide monitoring (Kayhanian et al., 2002) were applied to calculate nutrient loads from transportation.

Table 4-5 Nutrient EMCs for various land uses (VCSQMD, 2001; VCWPD, 2010 and 2011; and Kayhanian et al., 2002)

Land Use	Total Nitrogen (mg/L)	Total Phosphorus (mg/L)
Residential	4.57	0.54
Other Urban	3.13	0.70
Commercial	1.91	0.24
Industrial	3.78	0.5
Transportation	3.0	0.3

The calculated annual nutrient loads from stormwater runoff for each subwatershed are shown in Table 4-6. The total nitrogen load to Ventura River and its tributaries from stormwater runoff is estimated to be 90,320 lb/year. The total phosphorus load is estimated to be 11,616 lb/year.

Table 4-6 Wet-weather TN and TP loading (lb/year) from stormwater discharges

Subwatershed	TN Load (lb/year)	TP Load (lb/year)
Upper Watershed	1663	200
Reach 4	26,168	3224
Reach 3	3622	580
Lower Watershed	29,912	3887
San Antonio Creek	27,472	3470
Cañada Larga	1483	255
Total Load	90,320	11,616

4.1.1.2 Dry-weather loading from urban runoff

Dry-weather runoff from activities such as irrigation, sidewalk washing, and car washing can pick up nutrients and flow into storm drains, which then discharge to receiving waters. Nutrient loading from dry weather urban runoff was calculated with the equation:

$$\mathbf{L = Q \times C \times A \times 6.24\times10^{-5}} \qquad \textbf{Equation (2)}$$

Where:
L: Daily dry-weather pollutant load (lb/day)
Q: Flow rate (foot^3/acre/day)
C: Pollutant concentration (mg/L)
A: Area (acres)
6.24×10^{-5} = unit conversion factor (lb-L/foot^3-mg)

The dry-weather flow rate for urban runoff was obtained from the VCSQMP Meiners Oaks and Ojai outfall monitoring stations (VCSWQMP, 2010). The reported flow rate for both of these stations from an event on March 17, 2010 was 0.5 cfs. This flow was multiplied by the percent urban land use that drained to each site (61% at Meiners Oaks and 49% at Ojai) in order to exclude flow contribution from other land uses. Then, the flow was divided by the area that drained to each site and the average of the two area-weighted flows was calculated. The resulting average area-weighted urban flow rate is 26.98 foot^3/acre/day.

The concentrations of total nitrogen and total phosphorus in dry weather urban runoff were obtained from the VCWPD Meiners Oaks and Ojai outfall monitoring stations for 2010 and 2011. The number of dry-weather days in the Ventura River Watershed was estimated to be 331 days based on data collected from Ventura River County Water District Gage 020 from 1987 to 2007. Multiplying the number of dry-weather days by the calculated daily nutrient load results in estimated annual dry-weather loads of 19,180 lb/year of TN and 243 lb/year of TP. See Table 4-7.

Table 4-7 Dry-weather TN and TP loading (lb/year) from dry-weather urban runoff

Subwatershed	TN Load (lb/year)	TP Load (lb/year)
Upper Watershed	205	1.91
Reach 4	5172	50.2
Reach 3	929	19.9
Lower Watershed	6712	109
San Antonio Creek	5805	55.8
Cañada Larga	357	5.45
Total Load	19,180	243

4.1.2 Nutrient Loading from Ojai Valley WWTP Discharge

The Ojai Valley WWTP has capacity of 3.0 MGD of tertiary-treated wastewater. The Ojai Valley Sanitary District serves 5,600 acres of watershed and the treatment plant provides wastewater collection services for an estimated population of 23,000 people in the city of Ojai and in the communities of Meiners Oaks, Mira Monte, Oak View, Casitas Springs, and Foster Park.

Based on data collected from 2000 through 2012, Ojai Valley WWTP discharged tertiary-treated wastewater through an outfall at an average rate of 2.1 MGD into Ventura River. The discharge outfall is located approximately 3,000 feet upstream of the confluence of the Ventura River with Cañada Larga. The effluent concentrations of total nitrogen ranged from 2.6 mg/L to 21.1 mg/L, with an average of 5.86 mg/L. Nitrate-N was the dominant nitrogen compound, with concentrations ranging from 1.6 mg/L to 14.1 mg/L, and an average of 4.71 mg/L. Nitrite-N was generally below the detection limit of 0.1 mg/L. Ammonia-N was generally below the detection limit of 0.2 mg/L. Organic-N concentrations ranged from 0.2 mg/L to 12.7 mg/L, with an average of 1.1 mg/L. The total phosphorus concentration ranged from 0.062 mg/L to 5.7 mg/L, with an average of 1.38 mg/L. Phosphate-P was the dominant phosphorus compound, with concentrations ranging from 0.07 mg/L to 3.8 mg/L, and an average of 1.2 mg/L. (OVSD, 2000-2012).

The nutrient loading to Ventura River from Ojai Valley WWTP was estimated by multiplying the average effluent flow with average total nutrient concentrations (Table 4-8). The average annual loads of TN and TP were 37,475 lb/yr and 8855 lb/yr, respectively.

Table 4-8 TN and TP loading from Ojai Valley WWTP (OVSD, 2000-2012)

	Average Effluent Flow (MGD)	Average TN (mg/L)	Average TP (mg/L)	Average TN Load (lb/day)	Average TP Load (lb/day)	Average TN Load (lb/year)	Average TP Load (lb/year)
Ojai Valley WWTP	2.1	5.86	1.38	103	24.3	37,475	8855

4.2 Nonpoint Sources

Nonpoint sources in the Ventura River watershed include inputs from agricultural lands, horses and livestock, onsite wastewater treatment systems, groundwater, undeveloped open space, wildlife, and atmospheric deposition. This section provides an overview of each source and presents data to characterize each source.

4.2.1 Nutrient Loading from Agricultural Lands

Phosphorus and nitrogen that are applied to agricultural lands as fertilizer can be washed into receiving waters due to irrigation or stormwater runoff. In addition, nutrients applied to the land can migrate to groundwater, which in areas of groundwater upwelling, can also be a source of nutrients to surface water. As of April 2011, there were 143 agricultural land owners representing 4066 irrigated acres in the Ventura River watershed enrolled in the Conditional Waiver for Discharges from Irrigated Lands (Agriculture Waiver) through the Ventura County Agricultural Irrigated Lands Group (VCAILG). According to the 2010 annual monitoring report, avocado and citrus orchards are the predominate crops in the Ventura River watershed (VCAILG, 2011).

4.2.1.1 Wet-Weather Nutrient Loading from Agriculture

Equation 1 and the annual rainfall data in Table 4-3 were used to estimate the wet-weather nutrient loading from agricultural lands. A runoff coefficient of 0.1 (Ackerman and Schiff, 2003) was applied to agricultural land uses (including cropland/improved pasture, orchards/vineyards, nurseries, and other agriculture) in the Ventura River watershed.

Nutrient concentrations in wet-weather agricultural runoff were obtained from 2007, 2008, 2009, and 2010 VCAILG annual monitoring reports (Table 4-9). Data for orchards were obtained from the two VCAILG monitoring sites in the Ventura River. Because there are no VCAILAG monitoring sites in the Ventura River watershed that collect runoff from cropland/improved pasture, nurseries, and other agriculture, data from these land uses were obtained from VCAILG's Central Ditch monitoring site in the nearby Santa Clara River Estuary subwatershed. Since total nitrogen and total phosphorus concentrations are not reported, the concentration of nitrate is assumed as the concentration for total nitrogen, and the concentration of phosphate is assumed as the concentration for total phosphorus. This is a reasonable assumption because these two elements are generally applied to agriculture facilities in the form of synthetic fertilizer which are dominated by the biologically available form of the nutrient.

Table 4-9 Concentrations of nutrients in wet-weather runoff for various agricultural land uses (VCAILG, 2008, 2009, 2010, 2011)

Land Use	Nitrate (mg/L)	Phosphate (mg/L)
Cropland/Improved Pasture	19.83	1.40
Orchards	1.84	0.16
Nurseries	19.83	1.40
Other Agriculture	19.83	1.40

From Equation (1), the annual wet-weather nitrogen load from agricultural lands to the Ventura River and its tributaries is estimated to be 21,390 lb/year (Table 4-10) and the phosphorus load is estimated to be 1572 lb/year (Table 4-11).

Table 4-10 Annual wet-weather nitrogen loading (lb/year) from agricultural land uses

Subwatershed	Cropland/Improved Pasture	Orchard	Nursery	Other Agriculture	Total Load
Upper Watershed	0	5	0	72	76
Reach 4	4691	918	0	190	5799
Reach 3	1432	78	0	50	1560
Lower Watershed	910	135	30	87	1161
San Antonio Creek	6251	2511	111	738	9611
Cañada Larga	3093	19	0	71	3182
Total Load	16,376	3666	140	1207	21,390

Table 4-11 Annual wet-weather phosphorus loading (lb/year) from agricultural land uses

Subwatershed	Cropland/Improved Pasture	Orchard	Nursery	Other Agriculture	Total Load
Upper Watershed	0	0	0	5	5
Reach 4	332	80	0	13	425
Reach 3	101	7	0	4	112
Lower Watershed	64	12	2	6	84
San Antonio Creek	442	218	8	52	720
Cañada Larga	219	2	0	5	225
Total Load	1158	319	10	85	1572

4.2.1.2 Dry-Weather Nutrient Loading from Agriculture

Equation 2 was used to calculate dry-weather nutrient loading from agriculture. A dry-weather runoff rate was obtained from the Ventura County Farm Bureau based on water demand by crop type and consensus values for percent runoff from water applied (Farm Bureau, 2010). The resulting runoff rate of 16.85 $feet^3$/acre/day was used for the calculation of nutrient loads from cropland/improved pasture, nurseries, and other agriculture. The runoff rate from orchards is zero because no dry weather runoff has been measured at the two VCAILG monitoring sites, which drain orchards, in the Ventura River watershed.

Nutrient concentrations in dry-weather agricultural runoff were obtained from 2007, 2008, 2009, and 2010 VCAILG annual monitoring reports. Concentrations for orchards are zero based on the two VCAILG monitoring sites in the Ventura River. Data for cropland/ improved pasture, nurseries, and other agriculture were obtained from VCAILG's Central Ditch monitoring site. Central Ditch drains a more intensely farmed drainage area than the Ventura River watershed and, in addition to surface water runoff, receives discharges from tile drains, which concentrate nutrient concentrations. The average concentrations of nitrate and phosphate in dry-weather runoff from these crop types are 15.4 mg/L and 0.06 mg/L, respectively. Since total nitrogen and total phosphorus concentrations are not reported, the concentration of nitrate is assumed as the concentration for total nitrogen, and the concentration of phosphate is assumed as the concentration for total phosphorus.

The estimated dry-weather nutrient loads from agricultural lands are summarized in Table 4-12 and 4-13. The number of dry-weather days in the Ventura River Watershed was estimated to be 331 days. The dry-weather loading of TN and TP to the Ventura River and its tributaries is 10,389 lb/year and 41.2 lb/year, respectively.

Table 4-12 Dry-weather nitrogen loading (lb/year) from agriculture land uses

Subwatershed	Cropland/Improved Pasture	Orchard	Nursery	Other Agriculture	Total Load
Upper Watershed	0.0	0	0	26.0	0.0
Reach 4	2565	0	0	104	2565
Reach 3	904	0	0	31.5	904
Lower Watershed	703	0	22.8	67.1	703
San Antonio Creek	3663	0	64.9	432	3663
Cañada Larga	1765	0	0	40.3	1765
Total Load	9600	0.0	88	701	10,389

Table 4-13 Dry-weather phosphorus loading (lb/year) from agriculture land uses

Subwatershed	Cropland/Improved Pasture	Orchard	Nursery	Other Agriculture	Total Load
Upper Watershed	0	0	0	0.1	0
Reach 4	10.2	0	0	0.4	10.2
Reach 3	3.6	0	0	0.1	3.6
Lower Watershed	2.8	0	0.1	0.3	2.8
San Antonio Creek	14.5	0	0.3	1.7	14.5
Cañada Larga	7.0	0	0	0.2	7.0
Total Load	38.0	0.0	0.3	2.8	41.2

4.2.2 Nutrient Loading from Horses/Livestock

Manure produced by horses, cattle, and other livestock in the Ventura River watershed is a significant source of nutrients. Manure can be washed into receiving waters during wet weather and can also migrate to groundwater, which can thence be discharged to surface water. Manure can also be discharged to receiving waters in dry weather due to poor manure management or grazing activities that disturb stream banks and riparian areas and cause erosion, which increases the discharge of sediment, animal waste, and nutrients to surface waters.

According to SCAG data, there are about 357 acres of horse ranches in the Ventura River watershed (Table 4-1). In addition, there are low-density residential properties within the watershed with horses on the properties. The low-density residential acreage is not accounted for in estimating the horse ranch acreage in the watershed. The actual area of horse-impacted land uses may be greater than 357 acres.

According to SCAG data, there are 3.93 acres of dairy/intensive livestock land use in the watershed (Table 4-1). Based on 2007 US Department of Agriculture (USDA) Census data, it was determined that there are approximately 1940 cattle in the Ventura River watershed (USDA, 2009). According to the Ventura County Resource Conservation District, each cow needs approximately 30 acres of land and most cattle operations in the Ventura River watershed are on leased land (Melvin, 2012). Thus, the SCAG area does not represent all of the cattle grazing activities in the watershed. Therefore, this source assessment considered the California Department of Conservation's Farmland Mapping Program to determine the area of cattle grazing in the Ventura River watershed. Spatial data of the area in Ventura County suitable for grazing was clipped to the Ventura River watershed using GIS. The grazing data were then overlain with SCAG data to exclude areas that were obviously not used for grazing, such as oil and gas exploration and areas slated for development. The resulting area suitable for grazing in the Ventura River watershed (excluding Coyote Creek) is about 34,000 acres and generally overlaps with SCAG open space land use classifications.

4.2.2.1 Wet-Weather Nutrient Loading from Horses/Livestock

Equation 1 and the annual rainfall data in Table 4-3 were used to estimate the wet-weather nutrient loading from horses/livestock. A runoff coefficient of 0.50 was assumed for

dairy/intensive livestock and horse ranch land uses. A runoff coefficient of 0.06 was applied for grazing areas because, for the purposes of this source assessment, it was assumed that all grazing activities occurred on open space land uses.

Nutrient concentrations in wet-weather runoff from dairy/intensive livestock and horse ranch land uses were obtained from a 2007 study on wet-weather runoff from horse paddocks (Airaksinen, 2007). Runoff was collected from several areas of two paddocks during three different sampling periods. The lowest numbers reported for the spring sampling period were selected for this source assessment: 18.3 mg/L total nitrogen and 3.4 mg/L total phosphorus.

Nutrient concentrations in wet-weather runoff from cattle grazing were obtained from the USDA Measured Annual Nutrient loads from Agricultural Environments (MANAGE) database, which includes measured nitrogen and phosphorus load data published in scientific peer-reviewed studies. The mean concentrations for rangeland/pasture from the MANAGE database are 4.85 mg/L total nitrogen and 0.69 mg/L total phosphorus.
From Equation 1, the wet-weather total nitrogen loads to Ventura River and its tributaries were estimated to be 175 lb/year from dairy/intensive livestock, 15,141 lb/year from horse ranches, and 39,009 lb/year from cattle grazing (Table 4-14). The total phosphorus loads were estimated to be 32 lb/year from dairy/intensive livestock, 2813 lb/year from horse ranches, and 5557 lb/year from cattle grazing (Table 4-15).

Table 4-14 Wet-weather nitrogen loading (lb/year) from horses/livestock

Subwatershed	Dairy/Intensive Livestock	Horse Ranches	Grazing
Upper Watershed	0	630	0
Reach 4	175	4759	2591
Reach 3	0	351	5783
Lower Watershed	0	0	4877
San Antonio Creek	0	8598	11,100
Cañada Larga	0	802	14,658
Total Load	175	15,141	39,009

Table 4-15 Wet-weather phosphorus loading (lb/year) from horses/livestock

Subwatershed	Dairy/Intensive Livestock	Horse Ranches	Grazing
Upper Watershed	0	117	0
Reach 4	32	884	369
Reach 3	0	65	824
Lower Watershed	0	0	695
San Antonio Creek	0	1597	1581
Cañada Larga	0	149	2088
Total Load	32	2813	5557

4.2.2.2 Dry-Weather Nutrient Load from Horses/Livestock

Dry-weather nutrient loading from horses was estimated using the number of animals, manure production rates, and the amount of nutrients transported to surface waters. The dry-weather nutrient loading from cattle was not quantified. Instead, this source assessment contains a qualitative discussion of cattle as a source of dry-weather nutrient loading.

Loading from Horse Ranches

In 2009, Hawks & Associates conducted a preliminary survey of horses in the main Ojai Valley, which includes most of the Reach 4 and a large portion of the San Antonio Creek subwatersheds. The estimated total number of horses in the Ojai Valley ranged from 2000 to 3000. For the purposes of this source assessment, it was assumed that there were 2000 horses in the entire Ventura River watershed and the horses were allocated among each subwatershed based on area.

The manure production rates and associated nutrients were based on the American Society of Agricultural Engineers (ASAE) Manure Production and Characteristics Standard (ASAE, 2003), as summarized in Table 4-16. The unit waste production rate was multiplied by the number of horses to determine the nutrient loading from horses. It was then assumed that 10 percent of the manure is loaded to waterbodies via washwater, dumping, or when animals go near stream banks. TKN is assumed as the concentration for TN for the calculation of nitrogen load.

Table 4-16 Daily nutrient waste production rates for horses (ASAE, 2003)

Animal Type	Weight (lb)	TKN (lb/day)	Total P (lb/day)	PO4-P (lb/day)
Horse	1000	0.3	0.07	0.019

The number of dry-weather days in the Ventura River Watershed was estimated to be 331 days. Multiplying the dry-weather TN and TP loading per horse by the number of horses in the watershed and apportioning this loading throughout the subwatersheds, results in the dry-weather nutrient loading presented in Table 4-17.

Table 4-17 Dry-weather nutrient loading from horses in the Ventura River Watershed

Subwatershed	TN (lb/year)	TP (lb/year)
Upper Watershed	0	0
Reach 4	1187	281
Reach 3	3058	724
Lower Watershed	3159	748
San Antonio Creek	5449	1290
Cañada Larga	7007	1658
Total Loads	19,860	4700

Loading from Cattle

While cattle grazing can have a significant impact on dry-weather nutrient loading, the impacts are indirect and can be difficult to quantify. For example, when cattle are allowed to graze directly on streambanks, the bank structure can be destabilized, causing soil and associated nutrient loading into the stream. The loss of riparian vegetation also reduces shade and the buffering capacity of the stream. Finally, the loss of riparian vegetation and weakened streambanks decreases the depth and increases the width of the stream, which can increase its temperature. Such indirect effects impact the amount of nutrient loading to the stream and the stream's ecological response to the nutrient loading. The impacts will vary considerably depending on site-specific conditions such as vegetation cover, grazing density, proximity to the stream, and period of use (USEPA, 2003). Without site-specific data on ranching practices in the Ventura River watershed, dry-weather loading from cattle grazing cannot be quantified.

Dry-weather loading from intensive livestock/dairy land uses was not quantified either. The dry-weather impacts from intensive livestock/dairy land uses are similar to the impacts from both grazing activities and horse ranches. However, the number of cows associated with intensive livestock/dairy versus the number of cows associated with grazing is not known. From Table 4-1, the area of intensive livestock/dairy is negligible (4 acres) compared to the area estimated for grazing (34,000 acres) and the area of horse ranches (357 acres), so the relative contribution of dry-weather loading form intensive livestock/dairy is small and roughly accounted for in the dry-weather loading estimates for horses.

Regardless of the fact that there is no quantified source assessment for intensive livestock/dairy land uses and cattle grazing activities, this TMDL assigns both of these sources load allocations.

4.2.3 Nutrient Loading from Onsite Wastewater Treatment System

An Onsite Wastewater Treatment System (OWTS), or septic system, consists of a septic tank and a soil absorption field that allows effluent to infiltrate through soil. Septic systems can be significant sources of nutrients to subsurface and surface waters when they are not properly sited or functioning. Wastewater with high concentrations of nitrogen and phosphorus may seep into shallow groundwater and eventually enter surface waters. Nitrogen is particularly mobile in groundwater, while phosphorus has a tendency to be absorbed by the soils.

This source assessment relies on an estimate conducted by LWA of the total number of septic systems discharging within the Ventura River watershed (2,131). LWA created a list of parcels with structures having private or public restrooms where there are no sewer lines. The total number of septic systems was derived by subtracting the parcels where sewer services are available from all parcels. The map of sewered areas and parcels with possibly-existing septic systems in the Ventura River watershed is shown in Figure 4-2 (LWA, 2011). The resulting estimated number of 2131 is borne out by a review of septic system applications/permits to the Ventura County Environmental Health Division, which

shows 1422 septic systems in the Ventura River watershed. This represents the number of septic systems permitted by Ventura County. The number of commercial and multifamily septic systems permitted by the Regional Board is approximately 22. There are potentially more unpermitted septics systems in the Ventura River Watershed. Thus, the number of 2131 estimated by LWA is a good approximation of the total number of septic systems in the watershed.

OWTS may fail due to improper siting, design, and/or maintenance. Inadequate treatment may also result from insufficient vertical separation to the groundwater, insufficient horizontal separation to a surface water, or surface discharge from a failed disposal field. Nutrient loss rates to surface water of 32% nitrogen and 10% phosphorus were obtained from a nutrient groundwater/surface water interaction study for the Malibu Lagoon (Lai, 2009) and were applied for the calculation of nutrient loads.

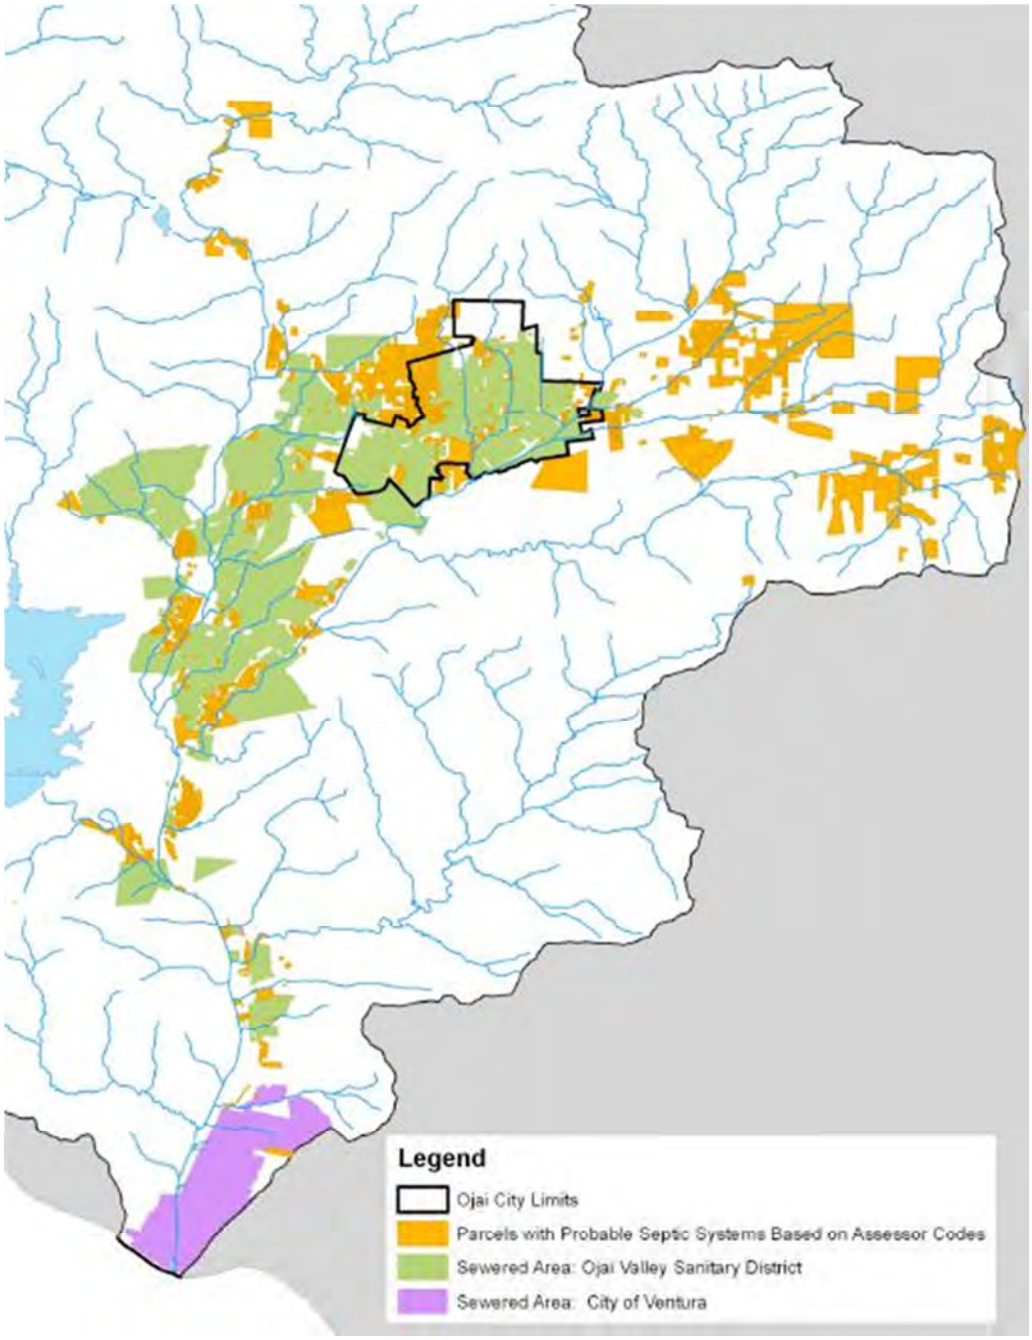

Figure 4-2 Potential OWTS in the Ventura River watershed (LWA, 2011)

The nutrient loads from septic systems were calculated assuming a daily average effluent flow rate of 200 gallons per household, and effluent nutrient concentrations of 36 mg/L nitrogen and 6 mg/L phosphorus (LWA, 2011). LWA estimated based the nitrogen and phosphorus concentrations on the average total nitrogen and phosphorus concentrations measured in Ojai Valley WWTP influent for the period of 1999-2008. The annual nutrient loading to the Ventura River watershed from OWTS is thus 14,955 lb-TN and 779 lb-TP.

4.2.4 Nutrient Loading from Open Space

Open spaces can contribute background nutrient loading due to decay of natural vegetation as well as nitrogen- and phosphorus-bearing rocks and soils. The nutrients are mobilized during wet-weather events or as groundwater discharge to surface waters.

4.2.4.1 Wet-weather loading from open space

Equation 1 and the annual rainfall data in Table 4-3 were used to calculate wet-weather nutrient loading from open space. A runoff coefficient of 0.06 was applied because of the largely pervious area that comprises natural undeveloped areas (Ackerman and Schiff, 2003). The pollutant concentrations in wet-weather runoff from open space were obtained from a SCCWRP study that measured total nitrogen and total phosphorus concentrations from 18 natural stream reaches across southern California (Yoon and Stein, 2008). The study collected total nitrogen and total phosphorus EMCs from two wet seasons between December 2004 and April 2006. The geometric means of all of the sampling events were 1.5 mg/L and 0.03 mg/L for total nitrogen and total phosphorus, respectively.

The open space area was adjusted by subtracting out the area that was used for the estimate of wet-weather loading from livestock grazing activities located in open space areas (Table 4-18).

Table 4-18 Adjusted open space areas

Subwatershed	Open Space (Acres)	Grazing Area (Acres)	New Open Space (Acres)
Upper Watershed	40,838	0	40,838
Reach 4 Watershed	8990	1833	7157
Reach 3 Watershed	4865	4722	143
San Antonio Creek	24,829	8414	16,414
Cañada Larga	11,721	10,820	901
Lower Watershed	5950	4878	1071

Using Equation 1, the wet-weather loading from open space is estimated to be 40,009 lb/year of total nitrogen and 750 lb/year of total phosphorus (Table 4-19).

Table 4-19 Wet-weather TN and TP loading (lb/year) from open space

Subwatershed	TN Load (lb/year)	TP Load (lb/year)
Upper Watershed	28,707	538
Reach 4	3340	62.6
Reach 3	57.8	1.1
Lower Watershed	354	6.6
San Antonio Creek	7148	134
Cañada Larga	403	7.6
Total Load	40,009	750

4.2.4.2 Dry-weather loading from open space

Equation 2 was used to calculate dry-weather nutrient loading from open space. Dry-weather flows from undeveloped areas are from interflow, rising groundwater, springs, and seeps. Dry-weather flows were obtained from USGS Gage 11116000 in North Fork Matilija from 1987-2007 as reported in the "Data Summary Report – Ventura River Watershed Hydrology Model" (Tetratech, 2008). The dry-weather flow was calculated as the median of reported monthly median flows for dry-weather months (April to October). The resulting flow (1.2 cfs) was then divided by the area that drains to USGS Gage 11116000 (9984 acres) to obtain an area-weighted open space dry weather flow of 10.38 cfs/acre/day.

The pollutant concentrations in dry-weather runoff from open space were obtained from a SCCWRP study that measured total nitrogen and total phosphorus concentrations from 22 natural stream reaches in dry weather across southern California (Stein and Yoon, 2007). The study collected nitrogen and phosphorus data from three dry seasons in spring 2005, fall 2005, and spring 2006. The geometric means of all of the sampling events were 0.33 mg/L and 0.05 mg/L for total nitrogen and total phosphorus, respectively. The number of dry-weather days in the Ventura River Watershed was estimated to be 331 days

From Equation 2, the annual dry-weather loads of TN and TP to Ventura River and its tributaries are estimated to be 6879 lb/year and 1042 lb/year, respectively (Table 4-20).

Table 4-20 Dry-weather TN and TP loading (lb/year) from open space

Subwatershed	TN Load (lb/year)	TP Load (lb/year)
Upper Watershed	2891	438
Reach 4	636	96.4
Reach 3	344	52.2
Lower Watershed	421	63.8
San Antonio Creek	1757	266
Cañada Larga	830	126
Total Load	6879	1042

4.2.5 Nutrient Loading from Groundwater Discharge

The Ojai Valley Basin, Upper Ojai Basin, Upper Ventura Basin, and Lower Ventura Basin are the major groundwater basins in the Ventura River watershed. The Ojai Basin is recharged where Thacher Creek, San Antonio Creek, and Reeves Creek enter the basin at alluvial fan heads (Tetratech, 2012). The groundwater is generally in an unconfined condition and recharge is primarily through percolation from active streambeds. However, a confining clay layer is located in the southwest corner of the basin along San Antonio Creek at depths of up to 200 feet where well may be artesian at times (LARWQCB, 2002).Groundwater from the Ojai Basin flows into the Upper Ventura River Basin and influences water quality there (VCWPD, 2010). A natural subsurface obstruction blocks subsurface flow below the Ventura River just above San Antonio Creek in the Casitas

Springs area, causing groundwater to rise as springs (LARWQCB, 2002). Water from the mainstem of the Ventura River recharges the Upper and Lower Ventura River Basins (Tetratech, 2012). Groundwater in the Upper Ventura Basin moves south through the alluvium, following the surface flow, and enters the Lower Ventura River subbasin below Foster Park (CDWR, 2004a). In the Lower Ventura River Subbasin, groundwater follows the course of the river to the Pacific Ocean (CDWR, 2004b).

Natural sources of nitrate in groundwater are due to decay of natural vegetation and nitrogen bearing rocks. Other than natural sources, surface water recharge, septic systems, and fertilizers and manure that migrate to groundwater via infiltration, are also causes of elevated nitrate concentrations in groundwater. No information is available on phosphorus concentrations in groundwater in the watershed.

Groundwater in the shallow alluvium provides the base flows to the Ventura River and its tributaries and is a major source of water during the dry season. Therefore, dissolved nutrients in groundwater have more significant impact during dry-weather periods.

In order to quantify the contribution of groundwater discharges to the main stem of the river, a groundwater budget based on estimates of the net gain or loss of groundwater in the Upper and Lower Ventura subbasins was used (Daniel B. Stephens & Associates, 2010).

According to this report, there is a net annual gain for the Upper Ventura subbasin for the budgeted time period (Water Years 1997 – 2007). It is thus not possible to calculate loading from groundwater discharges to surface water in the Upper Ventura subbasin. As described previously, there are other studies that document groundwater upwelling in the Upper Ventura subbasin, but none that provide a quantitative estimate of the amount of water that is discharged from groundwater to surface water. Thus, for the purposes of the TMDL source assessment, the amount of water that is discharged from groundwater to surface water was assumed to be zero over the entire Upper Ventura subbasin. This likely leads to an underestimate of the contribution of nutrient loading from groundwater in the upper portion of the Ventura River, especially given the variable and high concentrations on nitrate-nitrogen in surrounding wells (VCWPD, 2012).

The estimated groundwater discharge to surface water for the Lower Ventura River subbasin is 1,254 acre-feet/year or 1.73 cfs (Daniel B. Stephens & Associates, Inc., 2010). The average nitrate-N concentration is about 1.23 mg/L as measured in surrounding wells with depths from 30 to 100 feet (VCWPD, 2010). Therefore, the estimated nitrogen load to the Lower Ventura River subbasin is 4192 lb/year.

4.2.6 Nutrient Loading from Atmospheric Deposition

Atmospheric deposition is recognized as a potential source of nitrogen and phosphorus to coastal waters and watersheds in southern California. These pollutants are deposited by wet or dry deposition. Wet deposition refers to pollutants that are removed from the air by precipitation. Dry deposition occurs when pollutants settle out of the air and onto land or water surfaces. The two mechanisms of dry deposition are direct deposition (deposited directly onto a water surface) and indirect deposition (deposited onto surrounding land surfaces in the watershed and subsequently washed into surface waters). Direct atmospheric deposition is a very small proportion of the nutrient sources because the water surfaces of the Ventura River and its tributaries represent less than 1 % of the total watershed area. The much larger fraction of nutrient loading is by indirect deposition. The actual load attributed to indirect deposition is unknown because the fraction of deposited nitrogen and phosphorus that are consumed by terrestrial plants, transformed within the soils by bacteria, and abiotically degraded remains unquantified (Lu, et al., 2004). The contribution of nutrients by indirect deposition is accounted for in the wet-weather loading estimates for the various land uses described in the previous sections.

To calculate to the contribution of direct deposition during the dry-weather period, the length of the Ventura River, including its tributaries, is estimated to be 42 miles, and the average width of the river is approximately 20 feet. The surface area of the creek is thus approximately 0.16 square miles, or 41 hectares (ha). Because the deposition flux rate in the Ventura River watershed is not available, the mean dry deposition flux of total nitrogen (21.2 g/ha/day) in the Malibu Creek watershed is applied for calculation (Lu, et al., 2004). The resulting TN load is approximately 1.94 lb/day. The average dry-weather day in Ventura River watershed is 331 days. The annual nitrogen load from air deposition is thus approximately 534 lb/year. The general atmospheric deposition rate for total phosphorus is 1.64 g/ha/day (USEPA, 1994). The resulting TP load from air deposition is approximately 0.15 lb/day or 41 lb/year.

4.3 Summary of Source Assessment

A summary of the source assessment by sources/land use types is presented in Table 4-20. Based on available data and an estimation of nutrient loadings, stormwater and dry weather urban runoff via the MS4 contributes a large percentage of the nutrients to the Ventura River and its tributaries (21.3% in dry weather and 28.3% in wet weather). The Ojai Valley WWTP contributes a large portion of nutrient loading in dry-weather (37.6%) but a smaller portion in wet weather (1.7%). Horses/livestock and agricultural land uses contribute significant loading in both dry and wet weather. Open space loading is a significant source of nutrients in wet weather (19.1%) and a smaller source of nutrients in dry weather (7.6%). All sources of nutrients are assigned WLAs and LAs in the TMDL.

Table 4-21 Summary of TN loading for all sources/land uses in the Ventura River watershed

Source Type	TN (lb/year)	% total	% dry	% wet
Dry Weather				
Dry-weather Runoff from Urban Areas	19,180	6	21.3	n/a

5. LINKAGE ANALYSIS

Information on sources of pollutants provides one part of the TMDL analysis. To determine the effects of sources on water quality, it is necessary to also determine the linkage between the nutrient loading, expected in-stream water nutrient concentrations, and allowable amounts of algal biomass. This will define the assimilative capacity of the receiving water under critical conditions. This section describes the approach used to determine the nutrient loading that can be assimilated by Ventura River, its tributaries and the estuary, while ensuring attainment of the numeric targets (presented in Section 3) and protection of beneficial uses. This section also describes the critical condition.

5.1 Critical Condition

The critical condition is the period in which the receiving waterbody is most sensitive to the impacts associated with the pollutants of concern. The critical condition for the Ventura River and its tributaries, and the Estuary are evaluated separately.

5.1.1 Critical condition for the Ventura River and tributaries

As described in Section 2, the exceedances of the dissolved oxygen and biostimulatory substances water quality objectives caused by increased nutrient loading and eutrophication are a dry-season problem (May 1 to September 30). The ecology of algae in rivers is, in part, dependent on temperature and flow. An analysis of flow conditions in the Ventura River watershed (Tetratech, 2012) shows that flows vary depending on rainfall conditions, with highest flows at the end of winter and early summer due to receding baseflows from winter rains, and lowest flows at the end of summer and early winter. Dry-weather flows are highest in the upper watershed, both above and below the Matilija Dam (gages 603A and 602), and decrease lower in the watershed but above the Ojai WWTP (gage 607 in Reach 4 and gage 608 in Reach 3) due to evapotranspiration, infiltration, and water withdrawal. Storm flows are more consistent throughout the watershed, but are lower in Reach 4 than in Reach 3 and the upper watershed (Figure 5-1).

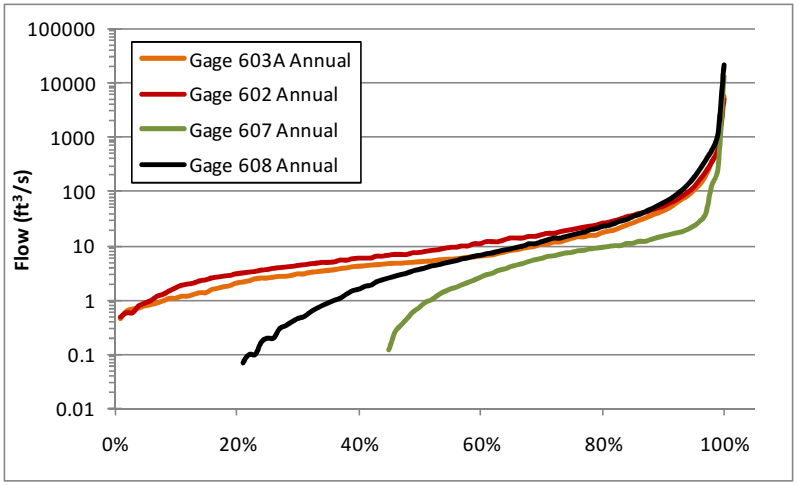

Figure 5-1 Distribution of Flows throughout the Ventura River (Tetratech, 2012)

Below gage 608, the Ojai WWTP is a significant source of water. The Ojai WWTP discharges to Reach 2 and regularly constitutes more than half the flow to the Estuary; 12 percent of the time it is 95 percent of the flow (Tetratech, 2012).

The critical condition in the Ventura River watershed occurs in dry season (May 1 to September 30) when flows are lowest and temperatures highest, creating favorable conditions for algae growth in the river.

Additionally, an analysis of nutrient uptake lengths (i.e. the average distance a nutrient molecule travels before being taken up by biota in the stream) in Ventura River demonstrated uptake lengths much longer than typically observed in small rivers. The summer uptake lengths for TN and TP were 3.6 km and 3.7 km, respectively. Typically, in small unimpaired streams, nutrient uptake lengths are on the order of meters not kilometers (Tetratech, 2012). The long nutrient uptake lengths indicate an ample supply of nutrients in the ecosystem – a nutrient molecule can travel a significant distance before it is taken up by biota in the system. Typically, when nutrients are in limited supply they are very quickly taken up and tightly recycled in the system resulting in very short uptake lengths. The long nutrient uptake length indicates that nutrients loaded in the upper watershed and tributaries have an impact on nutrients concentrations and biological response in the lower reaches; therefore, allocations are assigned to all sources throughout the watershed to attain numeric targets in all reaches and tributaries.

5.1.2 Critical Condition for the Ventura Estuary

The critical condition in the Estuary occurs during the dry season (May to October), when freshwater inputs dominate, temperatures are higher, and there is a higher probability of a berm forming at the Estuary mouth. A closed berm reduces flushing and increases the residence time of nutrients in the Estuary, which, as discussed in Section 2, are important co-factors affecting the Estuary's ecological response to nutrient loading.

An analysis was conducted on the hydrology of the Estuary (Tetratech, 2012). Flows to the Estuary were calculated by summing flows from Gage 608, Cañada Larga, and the Ojai Valley WWTP. It was determined that the majority of flows to the Estuary occur during winter months, except during drought years (e.g., 2006), due to the significance of wet-weather flows. However, it was also determined that the Estuary is directly connected to the ocean 81% of the time based on visual observations conducted by Ojai Valley Sanitation District between January 1999 and December 2003. When the Estuary was closed, it occurred during the months of July to October, during the dry season.

A predictive conceptual model was developed (Tetratech, 2012) based on the observation that the Estuary was usually closed when flows were less than 10 cfs and open when flows were greater than 10 cfs. It was assumed that a peak flow of 50 cfs was needed to open the Estuary, a flow of 10 cfs was needed to maintain a connection to the ocean, and a flow of less than 10 cfs for 30 days was needed for a berm to form and disconnect the Estuary from the ocean. When this model was applied to the flow record from 1982 to 2003, the Estuary was predicted to be closed 31% of the time. It is therefore concluded nutrients loaded to

the Estuary in wet weather do not remain in the Estuary because the Estuary is connected to the ocean during high flows.

Based on an assessment of the critical condition, which is the dry season, the linkage analysis for both the Ventura River and Estuary is conducted for dry-weather conditions. Basing the linkage analysis on *dry-weather* loading is a conservative approach to assessing conditions in the *dry season*. Nutrients are loaded from the watershed to the Ventura River and Estuary in both dry and wet weather (Section 4), but the nutrients loaded in the dry season are predominately responsible for the algae, eutrophic conditions, and nutrient impairments in the Ventura River, its tributaries and the estuary.

5.2 Linkage Analysis

5.2.1 Linkage Analysis for the Ventura River

The linkage analysis for the river is based on the River and Stream Water Quality Model (QUAL2K). QUAL2K is used to predict the nutrient concentrations and algal biomass in the various reaches of the Ventura River based on an estimate of watershed-based loading. Only the main stem of the river was modeled due to lack of data for the tributaries. QUAL2K is supported and distributed by the USEPA and has been widely used for studying the impact of conventional pollutants such as nutrients in streams. The QUAL2K model is suitable for simulating the hydrological and water quality conditions of a natural river or stream. It is a simple one-dimensional model that simulates basic stream transport and mixing processes. The processes employed in QUAL2K address nutrient cycles, algal growth, and dissolved oxygen dynamics. The complete description of the QUAL2K model, including model description, calibration and validation analysis, and model results, is included in Appendix B - Technical Memo – Algae and Nutrient Modeling for Ventura River.

5.2.1.1 Ventura River QUAL2K Model Development and Inputs

For modeling, the Ventura River mainstem was divided into 51 computational segments. Headwater data collected by UCSB in 2008 at the confluence of Matilija and North Fork Matilija Creeks (UCSB, 2009) were used to define the upstream boundary conditions for water quality parameters. Average flows from 2001-2008 compiled by Tetratech as part of development of the Ventura River Hydrology Model (Tetratech, 2008) were used to define the upstream boundary conditions for flow. (The model internally calculates the boundary conditions for each downstream segment.) San Antonio Creek, Cañada Larga and Ojai Valley WWTP were modeled as concentrated model inputs. San Antonio Creek and Cañada Larga flow data were obtained from average 2001-2008 data compiled by Tetratech for the 2009 hydrology model and water quality data were obtained from the 2008 UCSB study. For the Ojai Valley WWTP input, NPDES permit data were used to characterize water quality and flow. The watershed-based model inputs for all other sources were obtained from the TMDL source assessment (Section 4). Withdrawal from the Ventura River at Robles Diversion was modeled as an outflow. Meteorological conditions were represented by hourly data obtained from the NOAA weather station in Oxnard.

5.2.1.2 Ventura River QUAL2K Model Calibration and Validation

The model was run based on the inputs described previously. The predicted results of flow and in-stream water quality were compared to a set of data for calibration. The dataset was developed to create a full set of conditions representative of a typical dry-weather day. The water quality calibration data were obtained from the 2008 UCSB study for 14 points throughout the river, and the mean, minimum, and maximum values were calculated for comparison with model-predicted water quality. The model was calibrated for flow, nitrate, TN, phosphate, TP, and benthic algae. Figures 5-2 and 5-3 show the calibration results for flow and nitrate-nitrogen. The model was calibrated by adjusting model parameters to best fit the predicted and measured results.

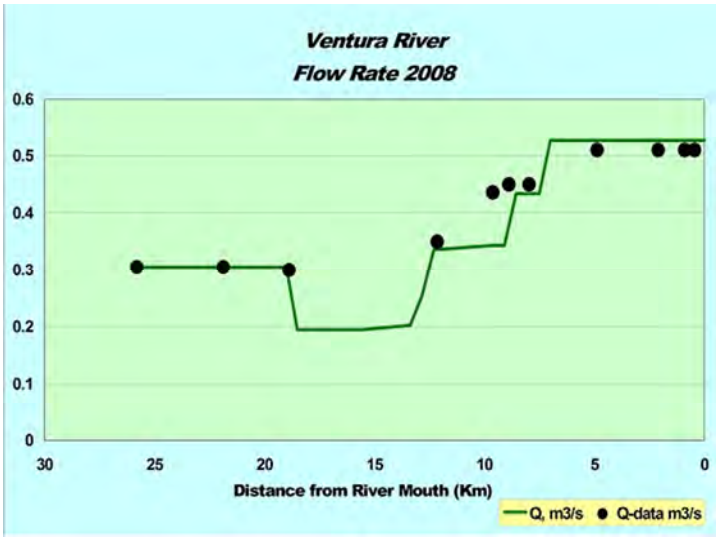

Figure 5-2 Comparison of calculated flow rate with 2008 observed data for calibration

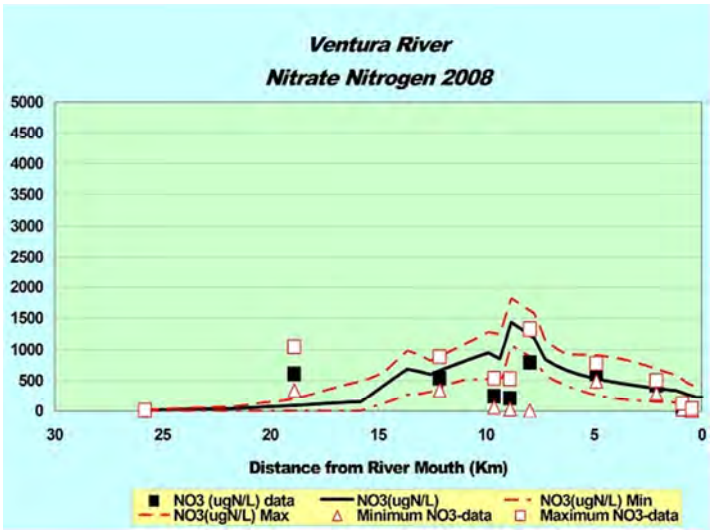

Figure 5-3 Comparison of calculated nitrate-nitrogen with 2008 observed data for calibration

To ensure that the model can reliably predict real situations, two additional sets of measured data, collected by SBCK Stream Team in 2006 and 2007, were used for model validation. The model parameters adjusted during calibration remained the same and only the inputs for San Antonio Creek, Cañada Larga and Ojai Valley WWTP were updated with 2006 and 2007 data. The model was validated for flow, nitrate and phosphate. No validation data were available for TN, TP, or algae. The model results show that flow and nutrient concentrations are validated reasonably well with the measured data (Figures 5-4 to 5-7).

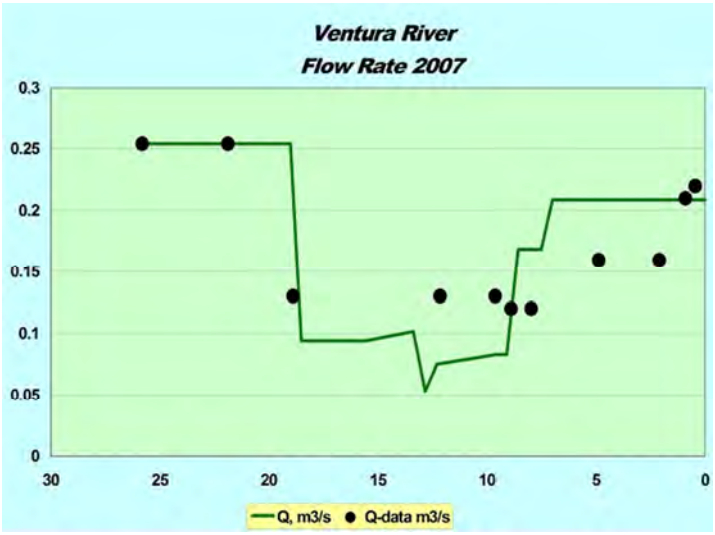

Figure 5-4 Comparison of calculated flow rate with 2007 observed data for validation

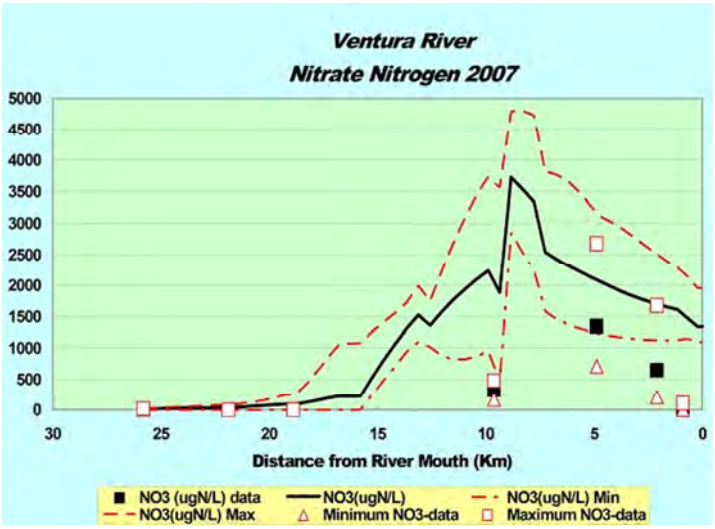

Figure 5-5 Comparison of calculated nitrate-nitrogen with 2007 observed data for validation

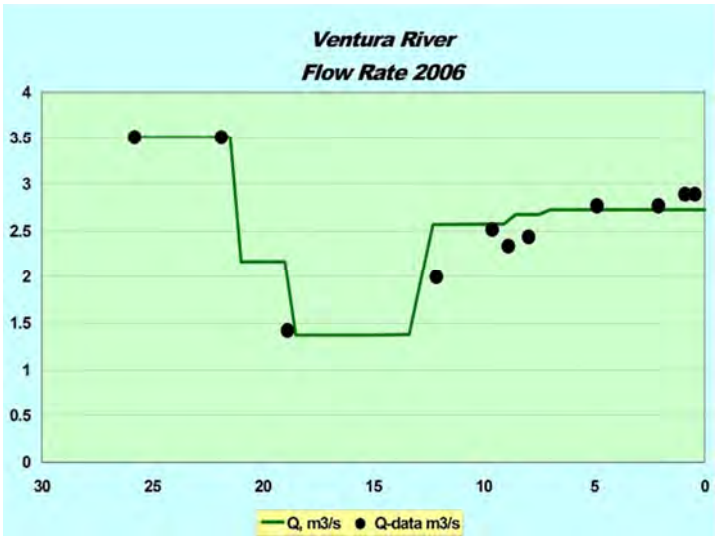

Figure 5-6 Comparison of calculated flow rate with 2006 observed data for validation

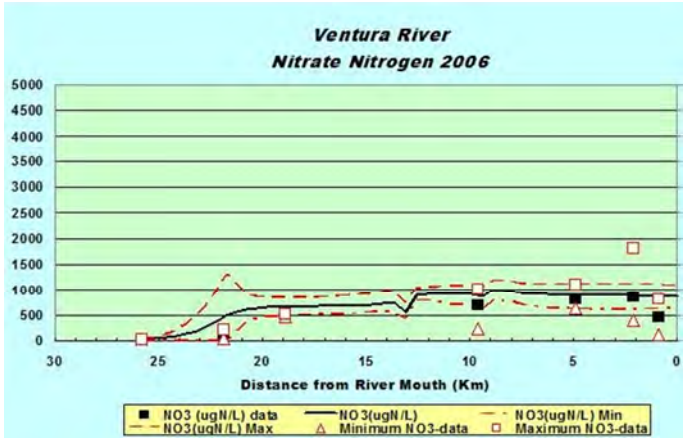

Figure 5-7 Comparison of calculated nitrate-nitrogen with 2006 observed data for validation

The model was able to successfully predict existing conditions (Figures 5-8 and 5-9). The model tracks the trend of in-stream measured water quality data and is approximately equal to the median of measured in-stream concentrations.

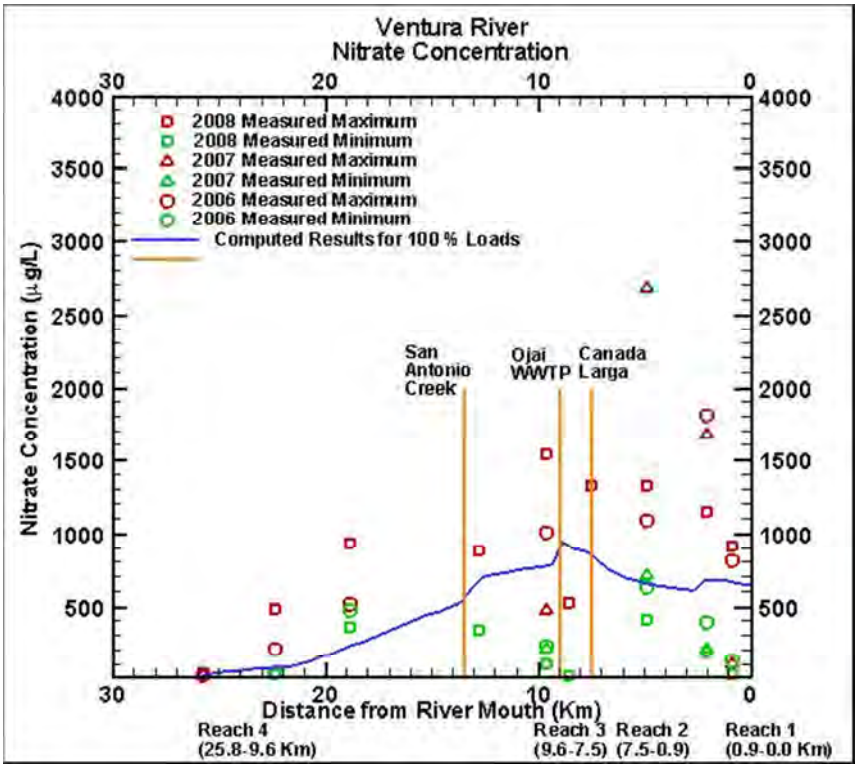

Figure 5-8 Predicted nitrate concentrations based on validated model

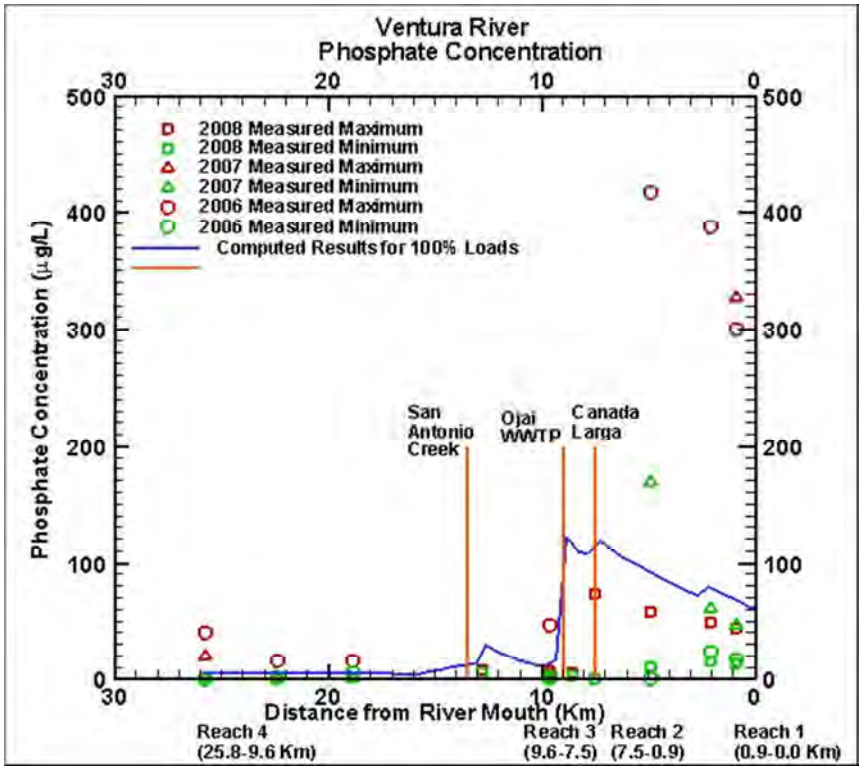

Figure 5-9 Predicted phosphate concentrations based on validated model

The results of the model were used to (1) determine allowable in-stream nutrient concentrations to meet algal biomass targets (Figure 5-10) and (2) evaluate various source reduction scenarios to set dry-weather load and waste load allocations (Section 6). An attempt was made to determine reach-specific relationships between allowable in-stream nutrient concentrations and algal biomass, but there were not enough reach-specific data to establish a significant relationship.

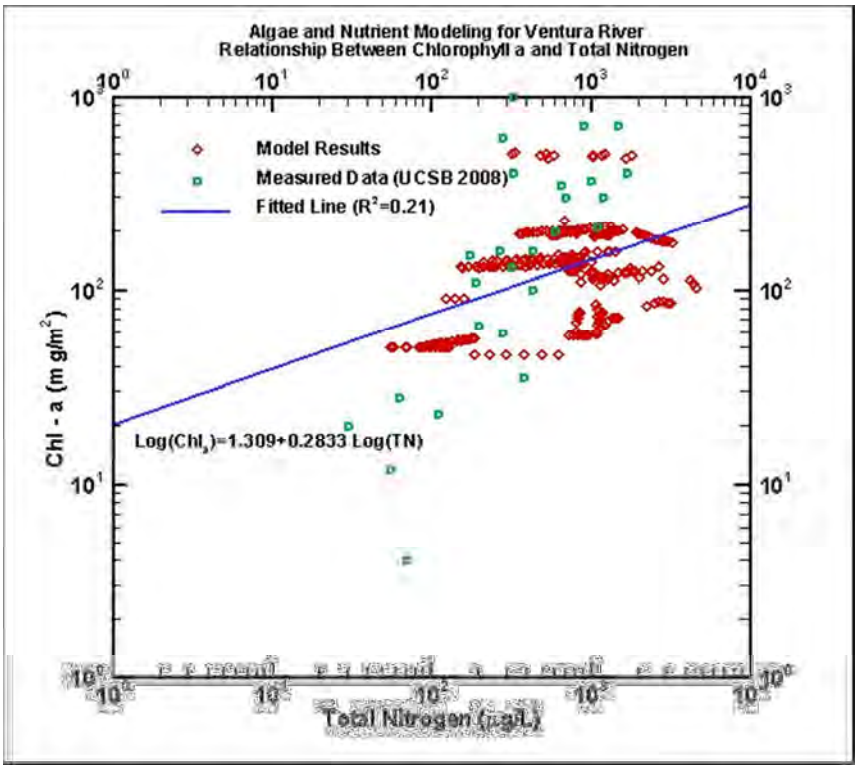

Figure 5-10 Relationship between chlorophyll a and total nitrogen in the Ventura River

The correlation between chl a and TN is based on a combination of both modeled data and measured data. This is because the measured data were obtained from just two sampling events during one year (2008), which does not capture the variability in algal biomass due to varying hydrological conditions (see, for example, Figure 2-18). The amount of algal biomass in the dry season is closely tied to severity of storms in the preceding winter season due to scouring of channels. The open channels created by large winter storms favor algal growth due to increased sunlight and temperature, but after several years with less rainfall, trees, shrubs and plants grow, which increase shading and inhibit algal growth (see, for example, Figures 2-19 and 2-20.) Therefore, modeled data, which were based on four years of data (2006-2008 and 2010) were used in addition to the 2008 measured data to represent a more complete set of hydrologic conditions. The use of the modeled data to supplement the measured data is appropriate because the model is able to successfully predict in-stream nitrate and phosphate (Figures 5-8 and 5-9). This correlation can be updated once a number of years of data have been collected that adequately bracket different hydrologic years, from drought conditions to high-flow years

5.2.2 Linkage Analysis for the Estuary

The linkage analysis for the Estuary is based on two lines of evidence that establish the relationship between nutrient loading to the Estuary and the resulting nutrient concentrations and algal biomass in the Estuary. The first approach uses the NNE BATHTUB spreadsheet modeling tool to establish the linkage between nutrient loading to the Estuary and the predicted water quality response. The second approach uses empirical relationships between nutrient loading and algal biomass in estuaries developed as part of the Southern California Bight Study 2008.

5.2.2.1 NNE BATHTUB Spreadsheet Modeling Tool

The NNE BATHTUB model was created for application to freshwater reservoirs and lakes. A simplifying assumption is made that the open water portion of the Estuary, formed by the closing of the berm in the late summer and early fall, acts like a freshwater reservoir. It is thus reasonable to apply BATHTUB to the Ventura Estuary during the critical condition.

The NNE BATHTUB spreadsheet tool was developed by Tetra Tech with support by US EPA Region IX and the State Water Resources Control Board. The NNE BATHTUB spreadsheet tool is a user friendly arrangement of the Army Corps of Engineers BATHTUB model (Walker, 1987, 1996) used to analyze the response of lake water quality to different nutrient loading situations. Tetra Tech configured the BATHTUB model to be used in an excel spreadsheet format. The model performs water and nutrient balance calculations under steady-state conditions. Eutrophication related water quality conditions are expressed in terms of total phosphorus, ortho-phosphorus, total nitrogen, inorganic nitrogen, chlorophyll a, transparency (Secchi depth), and hypolimnetic oxygen deletion rates. These conditions are predicted using semi-empirical relationships developed and tested on a wide range of reservoirs.

The following assumptions underlie the linkage analysis. Inputs to the Estuary include nutrient loading from the watershed as estimated by Tetratech by summing flows from Gage 608, Cañada Larga, and the Ojai Valley WWTP and multiplying them by median nutrient concentrations (Tetratech, 2012). Because the Estuary is connected to the ocean during wet-weather when the berm is breached, wet-weather flows do not remain in Estuary. The annual loading to the Estuary is thus assumed to be equal to the annual dry-weather load. During dry weather, evaporation and processes such as sedimentation, resuspension, and nutrient flux alter the concentrations of nitrogen and phosphorus in the Estuary. Nutrients in the system increase over the dry season, until the berm is breached during the following wet-weather season.

The NNE BATHTUB spreadsheet tool allows the user to input physical, chemical, and biological parameters. The input parameters are listed in Table 5-1. The model allows the user to analyze many different nutrient loading scenarios and evaluate the Estuary response. Likewise, the user may specify a chlorophyll-a concentration or change in Secchi depth and the model will predict the probability of exceeding the target under the

specified nutrient loading. Additionally, the model will show allowable nitrogen and phosphorus loading combinations to meet the target.

Table 5-1 Bathtub inputs

Parameter	Value
Volume	58,877 m^3
Surface Area	52,602 m^2
Mixed depth	80% of average depth
Evaporation Rate	63 in/ year
Secchi Depth	0.5 meters
Typical Chl-a	9.2 µg/L
TP Load	932 kg
TN Load	7,250 kg
Inorganic N	4,388 kg
Orthophosphate	954 kg
Inflow	6.56 hm^3

The volume and the surface area of the Estuary were calculated in consultation with SCCWRP using remote sensing data. A combination of light detection and ranging (LiDAR) and digital elevation model (DEM) data were used to estimate the bathymetry of the Ventura Estuary (Siebels, 2012, Appendix C).

First, the areal extent of the Estuary was defined based on wetlands polygons developed by SCCWRP using 2005 National Agriculture Imagery Program (NAIP) imagery and attributed using the Cowardin Classification system for wetlands. The polygons developed by SCCWRP were compared to National Wetlands Inventory data to verify the extent of the wetlands in the Ventura River Estuary. The polygons were then revised to delete one "riverine" polygon, redraw one unattributed polygon to align edges, and cut the uppermost polygons to fit the narrative description of the Estuary in Section 1. Although the revised polygons are based on 2005 NAIP imagery, they were also visually compared with 2010 and 2009 NAIP imagery, as well as observations of the Estuary by staff in 2011 and 2012, and historical photos of the Estuary from 1971 to 2010 obtained from the California Coastal Records Project. Based on these comparisons, it is found that the revised polygons present the typical areal extent of the Estuary (Figure 5-11).

Figure 5-11 Areal Extent of the Ventura River Estuary

The revised wetland polygons were then overlaid with LiDAR data to calculate the height of the estuary floor relative to the mean lower low water height. LiDAR data are preferred for estimating the height of the estuary floor because, unlike DEMs that use radar, LiDAR is able to penetrate through the water in the Estuary using light. DEM values were then used to estimate the height of the berm relative to the mean lower low water height. DEM values are preferred for estimating the height of the berm because the data are at a larger scale and average out the height and low points of the berm. The resulting height of the berm was determined to be 2.5 meters. It was assumed that a typical Southern California coastal estuary, when full, is 20 cm below the top of the berm (personal communication, Martha Sutula, SCCWRP, 2012). Thus, the water level of the Estuary is estimated at 2.3 meters. The depth of the Estuary was determined as the water level of the Estuary minus the height of the Estuary floor (Figure 5-12). The resulting volume is presented in Table 5-1.

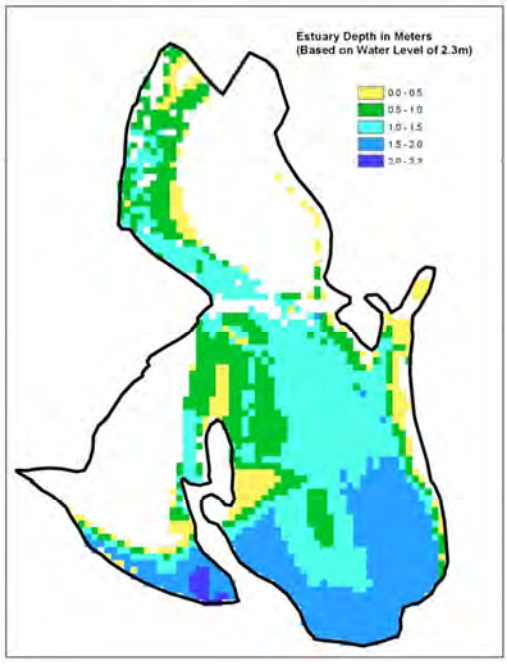

Figure 5-12 Estimated Depth of the Ventura River Estuary

The remaining inputs into the BATHTUB model are discussed as follows. BATHTUB calculates the average depth of the Estuary based on the input area and volume data. The mixing depth was conservatively assumed to be 80%. The evaporation rate was obtained from the El-Rio gage at the United Water Conservation District spreading grounds in Oxnard (Tetratech, 2012). The Secchi depth was based on a measurement collected by Regional Board staff in April 2012 by wading into the Estuary. It is likely that the Secchi depth is greater than the value reported in Table 5-1, and is probably equal to depth of Estuary (i.e., the bottom of the Estuary is visible). The typical chlorophyll a was obtained from an average of one measurement collected by Regional Board staff in April 2012, and two measurements collected by UCSB in 2008 (UCSB, 2009).

The loading and inflow inputs were obtained from the 2012 Tetratech report as previously discussed. The annual nutrient loads were calculated by multiplying the estimated median daily dry-weather loads by the number of dry-weather days in a year (318 days based on Tetratech's assumption that a dry day was any day it did not rain or it did not rain the day before.) The loading inputs obtained from the Tetratech report are lower than the predicted loading based on the freshwater model. (The freshwater model predicts an average load of 140 kg/day.) The loading estimates from the Tetratech report are based on the median dry-weather flow from long-term flow records, which reports lower flows to the estuary as compared to the predicted flows from the freshwater model. The freshwater model predicted load is based on three years of flow data (2006, 2007, and 2008) and tends to over predict nutrient loading due to higher predicted flows. This is because the three years of data used in the freshwater model do not reflect long-term cycles of wet years and drought conditions, as shown in Appendix B. However, the freshwater model does accurately predict in-stream nutrient concentrations; so it is clear that the difference in the loading estimates is related to flow and not nutrient concentrations. The Estuary linkage

analysis relied on the Tetratech report as the more accurate of the two loading estimates. The watershed reduction scenarios used to set allocations (Section 6) for the river will result in lower nutrient concentrations delivered to the estuary; thus, there will be an overall reduction in the nutrient load to the estuary.

5.2.2.2 Bathtub Model Results

There were not enough data to calibrate and validate the BATHTUB model for the Ventura Estuary. However, the predicted TN and TP concentrations were compared to limited data on existing TN and TP concentrations in the Estuary, including two samples collected by Regional Board staff in 2011 and 2012 and two samples collected by UCSB in 2008 (UCSB, 2009). The comparisons are shown in Table 5-2.

Table 5-2 BATHTUB-predicted phytoplankton and nutrient concentrations compared to measured nutrient concentrations

Predicted Chl-a µg/L	Predicted TP mg/L	Predicted TN (mg/L)	UCSB TP (mg/L)	UCSB TN (mg/L)	RB 2012 TP (mg/L)	RB 2012 TN (mg/L)	RB 2011 TP (mg/L)	RB 2011 TN (mg/L)
18.0	0.13	1.06	0.07	0.3	0.07	0.3	ND	1.02

As can be seen from Table 5-2, the existing loading from the watershed results in TN and TP concentrations in the Estuary that will attain the phytoplankton numeric target of 20 µg/L.

5.2.3 2008 Southern California Bight Study Relationships between nutrient loading and algal biomass

The second linkage approach for the estuary utilized the empirical relationships between algal biomass and estuarine nutrient loads developed with data from the 2008 Southern California Bight Regional Monitoring Program (Bight '08). The Bight '08 Eutrophication Assessment collected data on both response indicators and nutrient loading in 23 estuaries in southern California from November 2008 through October 2009 (McLaughlin K et al. Bight 2008 Regional Monitoring Program, 2012 Report). Statistical models were used to analyze the data and determine relationships between algal biomass and nutrient loads. The Bight 2008 was a regional assessment with data collected across many estuaries. Thus, when determining the relationships nutrient loads were normalized by estuarine area, volume, and residence time. Macroalgae and phytoplankton biomass both had significant positive relationships with nutrient loads. These relationships were used to evaluate nutrient loads and expected biological response in the Ventura River Estuary (McLaughlin K et al. Bight 2008 Regional Monitoring Program, 2012 Report).

The Bight '08 assessment developed several different equations evaluating the strength of various nutrient and algal biomass relationships; the relationships were strongest when estuary volume and residence time were taken into account (McLaughlin K et al. Bight 2008 Regional Monitoring Program, 2012 Report). The equations selected for this linkage

analysis were those that predict peak macroalgae biomass (R^2 = 0.1535, p value = 0.0.478) and annual average chlorophyll a (phytoplankton biomass) (R^2 = 0.0290, p value = .0.3959). The equation for peak phytoplankton biomass was not used because it was normalized to residence time only. Instead, the equation for average phytoplankton biomass was used because it was normalized for both residence time and volume and is consistent with the equation for peak macroalgae biomass. In addition, the data set for chlorophyll was limited and better suited for predicting an average phytoplankton biomass. Because the estuary is connected to the ocean during wet-weather when the berm is breached, wet-weather flows do not remain in the estuary. The loading and residence time are based on dry-weather conditions (TN dry-weather load = 22 kg/day, Residence Time = 2.97 days). The equations are presented below.

$$\log(Peak\ Macroalgae\ Biomass) = [0.15 * \log(\frac{Annual\ TN\ load}{365\ days} * res.time * \frac{1}{Estuary\ Vol})] + 1.7$$

$$\log(Annual\ Avg\ CHLa) = [0.10 * \log(\frac{Annual\ TN\ load}{365\ days} * res.time * \frac{1}{Estuary\ Vol})] + 0.82$$

5.2.3.1 Bight '08 Empirical Relationship Results

The results from the equations are presented in Table 5-3. The result for predicted annual average chlorophyll *a* is in good agreement with the limited measured data for chlorophyll in the estuary. The annual average chlorophyll *a* measured in the estuary is 9.2 µg/L; this is based on two samples collected by UCSB in the summer of 2008 and one sample collected by Regional Board staff in April 2012.

Additionally, based on thresholds presented in the Scanlan study (2007), described in the numeric targets section, (converted for dry weight, McLaughlin K et al. Bight 2008 Regional Monitoring Program, 2012 Report) estuaries with macroalgae biomass less than 70 grams of dry weight per meter squared are characterized with high to very high water quality at less than 15% cover. The numeric target macroalgae in this TMDL is set at ≤ 15 % cover. Thus, the current nutrient loading appears to attain the phytoplankton target for the estuary and limit macroalgae growth to acceptable levels. Moreover, the watershed loading reductions required to protect the river will reduce nutrient concentrations delivered to the estuary and ensure attainment of numeric targets and protection of beneficial uses.

Table 5-3 Predicted biological indicators based on Bight '08 Empirical Relationships

Biological Indicator	Predicted Result
Peak Macroalgae Biomass	50.8 (g dw/m^2)
Annual Avg. Chl. a	6.7 µg/L

6. POLLUTANT ALLOCATIONS AND TMDLs

This section explains the development of the loading capacity and allocations for nutrients in the Ventura River watershed. EPA regulations require that a TMDL include waste load allocations (WLAs), which identify the portion of the loading capacity allocated to existing and future point sources (40 CFR §130.2(h)) and load allocations (LAs), which identify the portion of the loading capacity allocated to nonpoint sources (40 CFR §130.2 (g)).

6.1 Dry-weather Allocations

As established in the problem statement and the linkage analysis, the critical condition for this TMDL is the dry season and it is loading in the dry season that results in water quality impairments. The allocations are thus primarily focused on dry-weather nutrient loading reductions. Basing the allocations on *dry-weather* loading is a conservative approach to addressing impairments in the *dry season*. Dry-weather is defined as a day with no rain. Wet-weather is defined as any day with rain.

Based on the relationship between nutrient concentrations and algal biomass obtained from the freshwater model (Figure 5-10), the allowable in-stream concentration of TN is equal to 1.15 mg/L. To maintain a balance of nutrients for biomass growth and prevent limitation by one nutrient or another, a ratio of total nitrogen to total phosphorus of 10:1 is used to derive the allowable in-stream concentration of total phosphorus equal to 0.115 mg/L (Thomann, Mueller, 1987).

The dry-weather allocations are based on an evaluation of several source reduction scenarios until one scenario was determined to result in in-stream nutrient concentrations that attain numeric targets for algal biomass, with an explicit margin of safety (Figures 6-1 and 6-2).

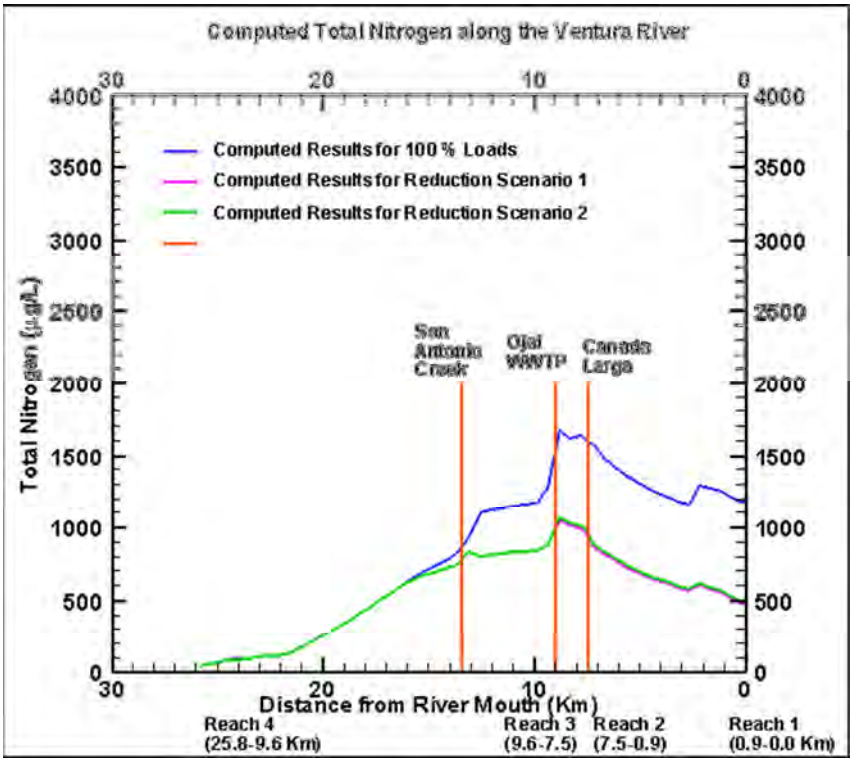

Figure 6-1 TN Reduction scenario to attain allowable in-stream TN concentrations

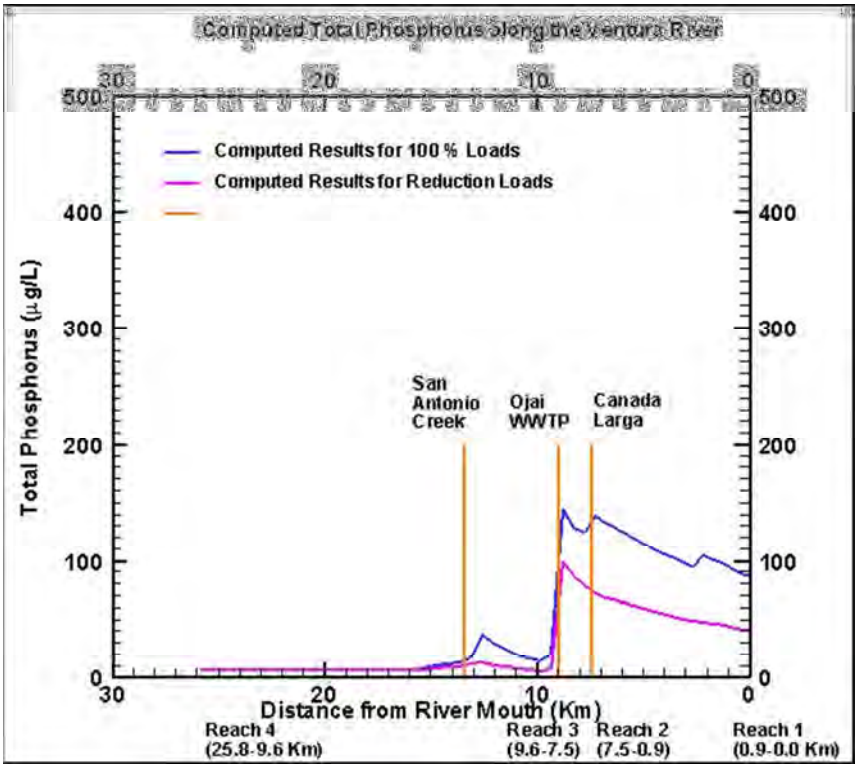

Figure 6-2 TP Reduction scenario to attain allowable in-stream TP concentrations

As described in the critical conditions section (Section 6), water quality impacts are due to watershed-wide loading of nutrients. Therefore, the reduction scenario was designed to reduce loads watershed-wide (Tables 6-1 and 6-2). The feasibility of implementation and the relative source contribution of each source were considered when assigning required load reductions. For example, the Ojai Valley WWTP can discharge slightly higher concentrations of TN in winter dry-weather (4 mg/L) than in summer dry-weather (3 mg/L) and still attain the required in-stream concentration of 1.15 mg/L TN (Figure 6-1, Reduction Scenario 2).

Table 6-1 Dry weather Allocation Scenario for TN

Source Type*	Existing Dry-Weather TN Load (lb/total dry days(331))	Allowable Dry-Weather TN Load (lb/total dry days(331))	Percent TN Reduction
Dry-weather WLAs for Ventura MS4	18,480	9,240	50%
Dry-weather WLAs for Caltrans	701	350	50%
Dry-weather WLAs for Ojai Valley WWTP	33,984	20,574	40%
Dry-weather LAs for Agriculture	10,389	5,194	50%
Dry-weather LAs for Horses/Intensive Livestock	19,860	199	99%
*Does not include allocation scenario for OWTS, General Stormwater permits, Grazing Activities, and Other NPDES permits. Allocations for all sources follow in subsequent tables/text.			

Table 6-2 Dry weather Allocation Scenario for TP

Source Type*	Existing Dry-Weather TP Load (lb/total dry days(331))	Allowable Dry-Weather TP Load (lb/total dry days(331))	Percent TP Reduction
Dry-weather WLAs for Ventura MS4	172	86.2	50%
Dry-weather WLAs for Caltrans	70.1	35.0	50%
Dry-weather WLAs for Ojai Valley WWTP	8030	5799	28%
Dry-weather LAs for Agriculture	41.2	20.6	50%
Dry-weather LAs for Horses/Intensive Livestock	4700	47	99%

*Does not include allocation scenario for OWTS, General Stormwater permits, Grazing Activities, and Other NPDES permits. Allocations for all sources follow in subsequent tables/text.

6.1.1 Dry-weather WLAs for Stormwater Sources

The identified reduction scenario is based on the assumption that TN and TP loading from dry-weather urban runoff from the Ventura County and Caltrans MS4s can be reduced by 50% based on reported removal efficiencies of structural and nonstructural BMPs (Section 7). The Ventura County MS4 annual monitoring reports document flows of less than 1 cfs at the Ojai and Meiners Oaks outfall monitoring sites. These flows are assumed for Caltrans facilities as well. These flows can be managed by standard structural and nonstructural BMPs that are consistent with the current MS4 permit obligations. Dry-weather WLAs shall be expressed as daily loads based on an estimated 331 dry-weather days per year (Table 6-3). Nutrient loading from stormwater sources is dependent on surface water runoff, which carries nutrients from the land to the river. The amount that is transported to the river is dependent on the amount of runoff, which is markedly different in dry weather and wet weather. The assignment of dry-weather and wet-weather WLAs reflects the difference in flow and corresponding nutrient loading under dry-weather and wet-weather conditions.

Table 6-3 Dry-weather WLAs for Ventura County MS4 and Caltrans

Source Type	Dry-Weather TN WLA (lb/day)	Dry-Weather TP WLA (lb/day)
Dry-weather WLAs for Ventura MS4	28	0.26
Dry-weather WLAs for Caltrans	1.1	0.11

6.1.2 Dry-weather WLAs for general industrial and construction stormwater permittees

The general industrial and construction stormwater permittees are prohibited from discharging non-storm water flows except as authorized by special conditions of statewide general permits. These special conditions require, for example, the inclusion of specific BMPs in pollution prevention plans and the prohibition of significant concentrations of pollutants. Therefore, dry-weather WLAs for general industrial and construction stormwater permittees are equal to the in-stream nutrient concentrations required to meet algal biomass numeric targets (Table 6-4).

Table 6-4 Dry-weather WLA for general industrial and construction stormwater permittees

Permittee	TN (mg/L) (annual dry-weather average)	TP (mg/L) (annual dry-weather average)
General Industrial Stormwater Permittees	1.15	0.115
General Construction Stormwater Permittees	1.15	0.115

6.1.3 Dry-weather WLAs for Ojai Valley WWTP

The dry-weather reduction assigned to Ojai WWTP is based on a report prepared for Ojai WWTP by MWH (2007) that contemplated TN limits equal to 3 mg/L and TP limits equal to 1 mg/L. In addition, based on comments from OVSD staff, the MWH report did not consider the impact of cooler winter temperatures on nitrogen treatment. The oxidation ditches at the plant rely upon a biological treatment process, which is affected by temperature and residence time. Thus, assigning WLAs during dry weather, without accounting for seasonal differences in summer dry-weather versus winter dry-weather performance does not reflect the operation of the plant. To account for seasonal differences in performance, it is assumed that after the upgrades described in the MWH implementation report are implemented, the Ojai WWTP can attain a TN concentration of 4 mg/L in winter dry weather. Because the critical condition is the dry *season*, it is possible to assign higher WLAs in winter dry *weather* and still attain required in-stream concentration of 1.15 mg/L in the dry *season* (see Figure 6-1, Reduction Scenario 2).

The required summer dry-weather seasonal WLA for TN was calculated as the product of 3 mg/L TN, the historical average daily flow (2000-2012), an 8.34 conversion factor, and the total number of summer dry-season days in a year (153 days). The required winter dry-weather WLA for TN was calculated as the product of 4 mg/L TN, the historical average daily flow, an 8.34 conversion factor, and the number of winter dry-weather days in a year (178 days, equal to 212 winter days – 34 wet days). The resulting summer dry-weather WLA (May 1 to September 30) is equal to 8,044 lbs and the resulting winter dry-weather WLA (October 1 to April 30) is equal to 12,477 lbs.

There is less of a seasonal effect on phosphorus treatment. Thus, Ojai WWTP receives a year-round dry-weather phosphorus WLA. The required mass-based WLA for TP was calculated as the product of 1 mg/L TP, the historical average daily flow, an 8.34 conversion factor, and the total number of dry-weather days in a year (331 days). Wet-weather days are excluded from the calculation. The resulting dry-weather WLA (year-round) is equal to 5,799 lbs. Assuming the treatment plant upgrades are implemented as described in the MWH report, the required reductions should be attained.

At the TMDL reconsideration, the Ojai WWTP allocation may be revised (i.e. increased) if the Ojai WWTP has accepted additional flows from other watershed sources. The Ojai WWTP will document and report annually the number, flow and TN load from watershed sources for the Regional Board to consider as part of the TMDL reconsideration.

6.1.4 Dry-weather LAs for Agriculture

The identified reduction scenario is based on the assumption that nutrient loading from dry-weather agricultural runoff can be reduced by 50% based on implementation of irrigation and nutrient management and dry-weather runoff treatment/infiltration BMPs (Section 7). Dry-weather LAs shall be expressed as daily loads based on an estimated 331 dry-weather days per year (Table 6-5). These allocations are consistent with the existing requirements

of the Agriculture Waiver adopted as Order No. 2010-0186. Nutrient loading from agriculture sources is dependent on surface water runoff, which carries nutrients from cropped areas to the river. The amount that is transported to the river is dependent on the amount of runoff, which is markedly different in dry weather and wet weather. The assignment of dry-weather and wet-weather WLAs reflects the difference in flow and corresponding nutrient loading under dry-weather and wet-weather conditions.

Table 6-5 Dry-weather LAs for Agriculture

Dry-Weather TN WLA (lb/day)	Dry-Weather TP WLA (lb/day)
16	0.06

6.1.5 Dry-weather LAs for Horse Facilities and Intensive Livestock Operations

Nutrient loading from horse facilities and intensive livestock operations is dependent on surface water runoff, which carries nutrients from the operations to the river. The amount that is transported to the river is dependent on the amount of runoff, which is markedly different in dry weather and wet weather. The assignment of dry-weather and wet-weather WLAs reflects the difference in flow and corresponding nutrient loading under dry-weather and wet-weather conditions. The reduction scenario assumes the elimination of dry-weather runoff from horse and intensive livestock facilities, represented as 1% of the existing load. As described in the source assessment section of the TMDL (Section 4), the estimated nutrient loading from horse facilities also approximates the nutrient loading from intensive livestock operations. Therefore, the source reductions for horse and intensive livestock facilities are jointly assigned. Nutrient contributions from horse and intensive livestock facilities are manageable in dry weather, considering the scale of the operations in the Ventura River watershed and the effectiveness of manure management practices at reducing dry-weather loading. Dry-weather LAs shall be expressed as daily loads based on an estimated 331 dry-weather days per year (Table 6-6).

Table 6-6 Dry-weather LAs for Horse Facilities and Intensive Livestock Operations

Dry-Weather TN WLA (lb/day)	Dry-Weather TP WLA (lb/day)
0.6	0.14

6.1.6 Dry-weather LAs for Grazing Activities

Nutrient loading from grazing activities is dependent on surface water runoff, which carries nutrients from grazed land to the river. The amount that is transported to the river is dependent on the amount of runoff, which is markedly different in dry weather and wet weather. The assignment of dry-weather and wet-weather WLAs reflects the difference in flow and corresponding nutrient loading under dry-weather and wet-weather conditions.

Dry-weather load reductions for grazing activities have not been quantified because their existing loading was not quantified. However, they are assigned a percent reduction of their existing TN and TP load equal to 10%. The existing load will be quantified as part of management plans required to implement the TMDL (see Section 7).

6.1.7 Dry- and Wet-Weather LAs for OWTS

LAs for OWTS were calculated based on an assumed reduction of TN loading equal to 50% based on requirements in the State Water Resources Control Board Policy for OWTS for supplemental treatment of certain OWTS in Tier 3, Impaired Areas. The resulting allowable load from OWTS is 7,478 pounds TN per year. The LAs are the same for dry and wet weather because there is little seasonal difference in loading from OWTS. No LAs are assigned to OWTS for TP.

6.1.8 Dry- and Wet-weather WLAs for Other NPDES Permittees

Dry-weather WLAs for other NPDES permittees are equal to the in-stream nutrient concentrations required to meet algal biomass numeric targets of 1.15 mg/L TN and 0.115 mg/L TP. Wet-weather allocations are set to attain site-specific nitrogen water quality objectives from Table 3-8 of the Basin Plan (Table 6-7). There are no site-specific objectives for Reach 1 or the Estuary, nor are there any "Other NPDES permittees" that discharge to Reach 1 or the Estuary. Thus, there are no wet-weather WLAs assigned to Other NPDES permittees for Reach 1 or the Estuary.

6.2 Wet-weather Allocations

6.2.1 Wet-weather allocations for Stormwater, Agriculture, and Horse/Livestock Sources

Based on the linkage analysis, wet-weather loads do not have a significant impact on receiving water quality in the Ventura River and its tributaries or the Estuary and biostimulatory objectives are attained. Thus, wet-weather allocations are set to attain site-specific water quality objectives from Table 3-8 of the Basin Plan (Table 6-7). There are no site-specific objectives for Reach 1 or the Estuary. For Reach 1 and the Estuary, wet-weather WLAs for stormwater sources are equal to existing water quality in stormwater discharges (maximum TN = 4.6 mg/L from Table 4-5) and LAs for agriculture and horse/livestock sources are equal to benchmarks of 10 mg/L nitrate-N + nitrite-N in the Agriculture Waiver.

Table 6-7 Wet-weather Allocations

Reach	Nitrate-N + Nitrite-N (mg/L)
Estuary	*
Reach 1	*
Reach 2	10
Cañada Larga	10
Reach 3	5
San Antonio Creek	5
Reach 4	5
Reach 5	5
*WLAs for stormwater are equal to 4.6 mg/ L TN and WLAs for agriculture and horse/livestock sources are equal to 10 mg/L nitrate-N + nitrite-N.	

6.2.2 Wet-weather Allocations for Ojai Valley WWTP

In wet-weather conditions, the biological performance of treatment operations at the Ojai Valley WWTP may be reduced due to lower temperatures and loading may increase due to increased inflows. Therefore, during wet-weather events, concentration-based WLAs are based on the 90th percentile of existing performance of the facility since 2000 (Table 6-8). Because the 90th percentile value is calculated based on the last 12 years of data, it includes older data prior to plant upgrades, and thus underestimates current performance (i.e., nutrient concentrations are higher); this results in attainable wet-weather WLAs.

Table 6-8 Ojai Valley WWTP Wet-weather WLAs

TN (mg/L)	TP (mg/L)
7.6	2.6

6.3 Margin of Safety

The sources of uncertainty in this TMDL are related to the selection of the algal biomass target, the relationship between nutrient concentrations and algal biomass in freshwater river systems and estuaries, the estimate of watershed-based nutrient loading, and the model-predicted water quality conditions in the receiving water. These areas of uncertainty are addressed with both an implicit and explicit margin of safety.

The implicit margin of safety includes conservative assumptions made when estimated watershed-based nutrient loading. For example, the nitrate and phosphate concentrations used to estimate dry-weather loading from agriculture is based upon measured data from an area more intensely farmed (and having tile drains, which concentrate nutrients) than in the Ventura River watershed. The flows for Canada Larga and San Antonio Creek were higher than the median flows obtained from long-term flow records. This overestimates the loading into the main stem of the river and conservatively predicts main stem nutrient concentrations. Finally, basing the allocations on dry-weather loading is a conservative approach to addressing impairments in the dry season. As presented in the TMDL the

water quality impairments are documented during the dry season, which is defined as May 1st – Sept. 30th. However, in southern California it is quite common to have warm springs (March, April) and/or warm falls (October, November); thus the dry-weather allocations work to protect the river during these periods and constitutes part of the TMDL implicit margin of safety.

The explicit margin of safety is calculated as the difference between the model-predicted maximum concentration in-stream after implementation of reduction scenarios and the desired in-stream concentrations of 1.15 mg/L TN and 0.115 mg/L TP. The resulting explicit margin of safety is 7%. This explicit margin of safety is applied to account for uncertainty in the algal biomass numeric target of 150 mg/m^2 and the relationship between the required in-stream nutrient concentrations necessary to attain this value. This explicit margin of safety also addresses the fact that the model-predicted nutrient concentrations are reflective of median measured concentrations, and do not capture not maximum concentrations (Figures 5-8 and 5-9).

7. IMPLEMENTATION

This section describes the regulatory mechanisms that will be used to implement the TMDL, how compliance with WLAs and LAs will be determined, implementation measures that could be used to attain WLAs and LAs, and an implementation schedule. This section also includes a discussion of monitoring requirements, special studies that may be conducted to evaluate assumptions in the TMDL, and a consideration of costs of the reasonably foreseeable methods of compliance with the TMDL.

7.1 Implementation of WLAs

The regulatory mechanisms used to implement the WLAs include the Ojai Valley WWTP NPDES permit, the Ventura County MS4 NPDES permit, the Caltrans MS4 NPDES permit, the general industrial storm water permits, the general construction storm water permits, and other NPDES permits. Effluent limits consistent with the assumptions and requirements of the WLAs shall be incorporated into each permit, following the effective date of this TMDL, at the time of permit issuance, modification, or renewal of the permit.

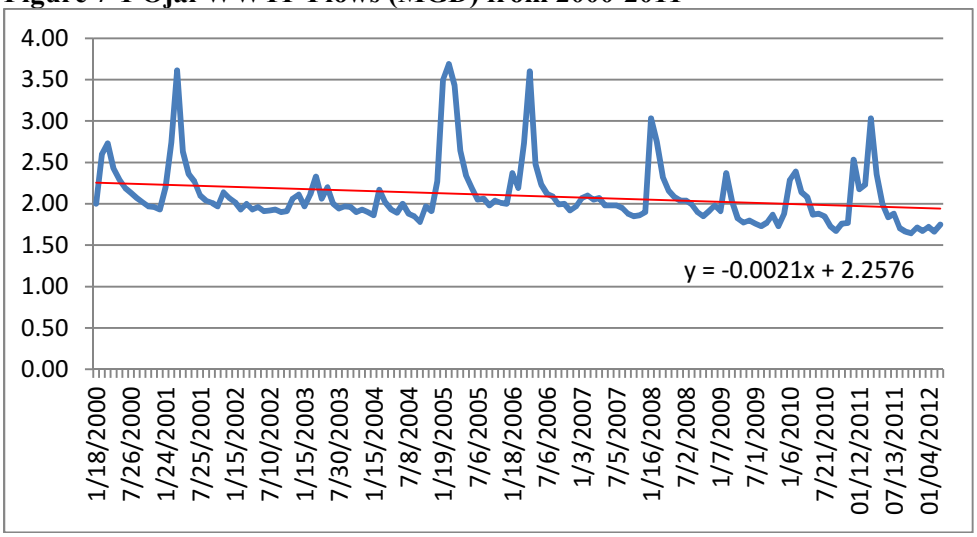
7.1.1 Ojai Valley WWTP

The TN WLAs for the Ojai WWTP shall be incorporated into the permit as seasonal numeric effluent limitations. The summer dry-weather effluent limitation shall be equal to the summer dry-weather WLA of 8,044 lbs/season (May 1 to September 30). Compliance with the summer dry-weather effluent limitation shall be determined by calculating the sum of the products of the monthly average TN concentration and the daily flow for each dry-weather day, over the summer season. The winter dry-weather WLA and wet-weather WLA shall be combined into a single concentration-based winter season effluent limitation, calculated as the weighted average of 4 mg/L (the allowable winter dry-weather concentration) and 7.6 (the allowable wet-weather concentration), based on the assumption that there are 178 winter dry-weather days and 34 wet-weather days in a year. The resulting concentration of 4.6 mg/L shall be expressed as a monthly effluent limitation from October 1 to April 30. This calculation is consistent with the assumptions and requirements of the winter dry-weather and wet-weather WLAs.

For TP, compliance with the dry-weather WLA-based effluent limitation shall be determined by calculating the sum of the products of the monthly average TP concentration and the daily flow for each dry-weather day, over an annual period. Wet-weather days shall be excluded from the dry-weather WLA compliance determination.

Based on the mass-based allocation scenario, it is possible that if flows approach the design capacity of 3 MGD, the Ojai WWTP will have to reduce concentrations of nutrients below 3 mg/L TN and 1 mg/L TP in order to attain WLAs. However, it is not expected that flows will increase significantly during the permit cycle; as result of very slow growth in the watershed, flows discharged from the Ojai WWTP have been constant, and have even slightly decreased, over the last 12 years (Figure 7-1). Thus, it is expected that Ojai WWTP will attain mass-based WLA-based effluent limitations.

Figure 7-1 Ojai WWTP Flows (MGD) from 2000-2011



In addition, the TMDL will be revised to adjust the allocation scenario and increase the allocation for the Ojai WWTP if the Ojai WWTP takes additional flows from other sources in the watershed such as septic systems in order to achieve the TMDL. The Ojai WWTP will document and report annually the number, flow and TN load from watershed sources for the Regional Board to consider as part of the TMDL reconsideration.

The wet-weather WLAs shall be incorporated as numeric effluent limitations, expressed as a daily maximum concentration, to be assessed at a minimum with monthly sampling during months when rain occurs. Ojai WWTP shall achieve compliance with wet-weather WLAs upon incorporation into the permit.

Ojai WWTP shall achieve compliance with dry-weather WLAs within 10 years of the effective date of the TMDL. Ojai Valley WWTP shall submit justification for an implementation schedule up to 10 years as part of their report of waste discharge in accordance with the Compliance Schedule Policy. Ojai Valley WWTP shall have interim dry-weather WLAs based on current plant performance (90^{th} percentile of the last twelve years of data); i.e., equal to wet-weather WLAs (Table 7-1). Because the 90^{th} percentile value is calculated based on the last 12 years of data, it includes older data prior to plant upgrades, and thus underestimates current performance (i.e., nutrient concentrations are lower); this results in attainable interim WLAs. The interim WLAs apply in both winter dry weather and summer dry weather.

Table 7-1 Ojai Valley WWTP interim dry-weather WLAs

TN (mg/L)	TP (mg/L)
7.6	2.6

7.1.2 Ventura County MS4 and Caltrans

The WLAs for the Ventura County MS4 permittees and Caltrans shall be incorporated into the permit as numeric water quality-based effluent limitations. Permittees may be deemed in compliance with water-quality based effluent limitations if they demonstrate that (1) there are no violations of the water quality-based effluent limitation at the Permittee's applicable MS4 outfall(s); or (2) there is no direct or indirect discharge from the Permittee's MS4 to the receiving water during the time period subject to the water quality-based effluent limitation.

Wet-weather numeric effluent limitations shall be expressed as event mean concentrations and shall apply immediately upon issuance, modification, or renewal of the permits. Compliance with wet-weather WLAs shall be assessed at a minimum with two wet-weather sampling events. If permittees provide a quantitative demonstration that watershed control measures and BMPs will achieve wet-weather water quality-based effluent limitations, then compliance with wet-weather water quality-based effluent limitations can be determined by satisfactory implementation of those actions, subject to Executive Officer approval.

Dry-weather WLAs shall be assessed at a minimum with quarterly sampling and shall be attained within 6 years. Compliance will only be assessed on the day of sampling. Dry-weather sampling may occur 72 hours after a storm event. The 6-year dry-weather implementation schedule is based on the estimated time needed to eliminate or treat the very low dry-weather storm drain flows observed in the watershed using standard structural and nonstructural BMPs that are consistent with the current MS4 permit obligations. If necessary, in order to request additional time to attain dry-weather WLAs, permittees shall demonstrate that they have effectively pursued design, permitting, and construction of necessary BMPs prior to the five-year TMDL reconsideration.

Consistent with the assumptions of the dry-weather waste load allocations, compliance may be demonstrated with area-weighted effluent limitations. Area-weighted effluent limitations should be 0.0025 lb/day/acre TN and 2.3×10^{-5} lb/acre/day TP for the Ventura County MS4, and 0.0042 lb/acre/day TN and 4.2×10^{-4} lb/acre/day TP for Caltrans, derived by dividing the daily loads by the total land use area in the watershed covered by their respective permits (11,085 acres for the Ventura County MS4 and 251 acres for Caltrans, excluding the Coyote Creek subwatershed).

Ventura County MS4 permittees and Caltrans shall provide an implementation plan to the Regional Board outlining how they intend to achieve compliance with the WLAs. The report shall include implementation methods, an implementation schedule, proposed interim milestones, and compliance points. The report shall provide reasonable assurance that implementation methods will be sufficient to achieve the WLAs.

7.1.3 General Industrial and Construction Stormwater Permittees

The dry- and wet-weather WLAs for the general and industrial stormwater permittees shall apply immediately upon permit issuance, modification, or renewal and shall be incorporated into permits as numeric effluent limitations. Wet-weather numeric effluent limitations shall be expressed as event mean concentrations and dry-weather numeric effluent limitations shall be expressed as instantaneous maximums. Compliance with wet-weather WLAs shall be assessed at a minimum with one wet-weather sampling event. Compliance with dry-weather WLAs shall be assessed at a minimum by averaging the results of two grab samples.

7.1.4 Other NPDES Permittees

The dry- and wet-weather WLAs for other NPDES permittees shall apply immediately upon permit issuance, modification, or renewal of applicable permits and shall be incorporated into permits as numeric effluent limitations. Wet-weather numeric effluent limitations shall be expressed as event mean concentrations and dry-weather numeric effluent limitations shall be expressed as instantaneous maximums. Compliance with wet-weather WLAs shall be assessed at a minimum with one wet-weather sampling event. Compliance with dry-weather WLAs shall be assessed at a minimum with two grab samples.

7.2 Implementation of LAs

Two primary federal statutes establish a framework in California for addressing nonpoint source water pollution: Section 319 of the Clean Water Act (CWA) of 1987 and Section 6217 of the Coastal Zone Act Reauthorization Amendments of 1990 (CZARA). In accordance with these statutes, the state assesses water quality associated with nonpoint sources of pollution and develops programs to address nonpoint sources. The *Plan for California's Nonpoint Source Pollution Control Program* (NPS Program Plan), which became effective in 2000, provides a coordinated statewide approach to dealing with nonpoint source pollution. Federal approval of the NPS Program Plan required the State Water Resources Control Board (SWRCB) to provide assurances that it has the legal authority to implement and enforce the NPS Program Plan. In 2004, the SWRCB adopted the Nonpoint Source Implementation and Enforcement Policy. This policy specified that the regional boards have the administrative permitting authorities to regulate nonpoint sources of pollution through Basin Plan discharge prohibitions, waste discharge requirements (WDRs), and waivers of WDRs. The regulatory mechanisms that will be used to implement LAs for each source category are described below.

7.2.1 Agricultural Discharges

The LAs for irrigated agricultural lands shall be implemented through the Agriculture Waiver or other appropriate Regional Board order. Under the existing Agriculture Waiver (Order No. 2010-0186), growers are required to monitor discharges and, if water quality exceeds objectives, growers are required to develop a water quality management plan and

implement best management practices (BMPs) to attain objectives. Each owner and/or operator of irrigated agricultural lands in the Ventura River Watershed shall be required to enroll in the Agriculture Waiver or other Regional Board order in order to comply with the LAs. Agricultural lands shall achieve compliance with dry- and wet-weather LAs within 6 years of the effective date of the TMDL.

The existing monitoring program for the Agriculture Waiver includes two monitoring sites in the upper watershed that monitor runoff from orchards. To implement the LAs in this TMDL, the monitoring program shall be revised to add representative sites in the lower watershed to monitor runoff from other crop types. In addition, VCAILG shall work with the Regional Board staff to relocate monitoring sites in the upper watershed to better assess potential dry-weather runoff from agriculture. The existing monitoring program for the Agriculture Waiver requires two dry-weather and two wet-weather sampling events. In order to implement the dry-weather LAs, dry-weather sampling may occur 72 hours after a storm event. The revised monitoring program shall be subject to approval by the Executive Officer of the Regional Board.

To assist in implementation of LAs, area-weighted benchmarks can be applied; if used, they shall be 0.008 lb/day/acre TN and 3.2×10^{-5} lb/acre/day TP, derived by dividing the daily loads by the total agriculture area in the watershed (1971 acres, excluding orchards and the Coyote Creek subwatershed).

Order No. 2010-0186 states, "It is expected that source control management practices, such as improved irrigation efficiency and fertilizer management, employed by Dischargers to attain surface Water Quality Benchmarks will reduce loading to groundwater as well." To implement this TMDL, the VCAILG water quality management plan shall specify that all growers in the Ventura River watershed shall implement nutrient-related source control BMPs. If the LAs are implemented in another Regional Board order in the future, then that order shall require growers in the Ventura River watershed to implement nutrient-related source control BMPs.

7.2.2 OWTS

The LAs for OWTS shall be implemented through discharge prohibitions, WDRs, or waivers of WDRs. Commercial and multifamily OWTS are currently regulated by the Regional Board through WDRs. Single family residential OWTS are currently regulated by the City of Ojai, the City of Ventura, and the County of Ventura, as specified in memorandums of understanding (MOUs) with the Regional Board, in order to implement a waiver of WDRs for single family residential OWTS adopted by the Regional Board in 2004. The MOUs require the Regional Board to evaluate the local agency every five years to ensure their municipal plumbing code and OWTS program is substantially equivalent to any statewide standards adopted pursuant to CWC sections 13290 and 13291.

CWC sections 13290 and 13291 require that the SWRCB adopt statewide regulations for the permitting and operation of OWTS (OWTS Policy). SWRCB adopted a policy to comply with CWC sections 13290 and 13291 on June 19, 2012. The OWTS Policy will become final and in effect once it is approved by the Office of Administrative Law. The

policy emphasizes local management of OWTS. The policy requires an Advanced Protection Management Program and local agencies are authorized to implement Advanced Protection Management Programs in conjunction with their existing programs and in collaboration with the Regional Board. The geographic area for the Advanced Protection Management Programs to implement this TMDL shall initially be the entire Ventura River watershed because the TMDL applies to all reaches and tributaries of the Ventura River and because of the demonstrated connectivity between groundwater and surface water throughout the watershed.

The OWTS in the Ventura River watershed fall under Tier 3 of the OWTS Policy. The Regional Board will work with local agencies to determine which existing OWTS or areas of OWTS are contributing to the overall loading from OWTS as described in the source assessment (Section 4). Areas found not to be contributing to the overall loading may be removed from the Advanced Protection Management Program as approved in a Local Agency Management Program. Existing OWTS are required to be upgraded or modified to enhance their nitrogen removal or meet other requirements of the Advanced Protection Management Program if it is determined they are contributing to the impairment, and are subsequently covered under approved special provisions of a Local Agency Management Program, or the Regional Board issues subsequent orders requiring upgrades or modifications. Existing OWTS will remain regulated by existing MOUs and future Local Agency Management Programs until the above determination is made and subsequent upgrades are required.

New or replacement OWTS installations, as defined by the OWTS Policy upon its becoming effective, that are within the Advanced Protection Management Program area, shall meet the supplemental treatment requirements for nitrogen per Tier 3 of the OWTS Policy.

The Regional Board will evaluate the existing MOUs and any future submittal of a Local Agency Management Program under the OWTS Policy with the City of Ventura, the City of Ojai, and the County of Ventura to determine if their OWTS programs need to be updated to reflect the OWTS Policy, or if additional changes are needed to implement the LAs. OWTS dischargers shall achieve compliance with dry- and wet-weather LAs within 10 years of the effective date of the TMDL.

7.2.3 Horse and Livestock Activities

The LAs for horse and livestock facilities shall be regulated by WDRs or waivers of WDRs. It is expected that a waiver program similar to the Agriculture Waiver will be adopted for horse and livestock activities. As part of the proposed program, horse and livestock facilities shall be required to conduct monitoring and develop management plans that will assess baseline water quality discharged from their facilities, determine reductions needed to attain LAs, and implement management measures to attain LAs.

Compliance with LAs will be demonstrated at monitoring sites approved by the Executive Officer of the Regional Board through the monitoring program developed as part of the waiver or WDR, or through a monitoring program that is required to implement this TMDL

in the event a waiver or WDR is not adopted in accordance with the TMDL implementation schedule. Horse and livestock facilities shall achieve compliance with dry- and wet-weather LAs within 10 years of the effective date of the TMDL.

7.3 Potential Implementation Strategies and Associated Costs

The TMDL requires responsible parties to attain WLAs and LAs for nutrients to prevent excessive algal growth and maintain adequate dissolved oxygen concentrations and pH values in the Ventura River and its tributaries. There are many implementation alternatives available to reduce nutrient loading. Rather than a single treatment solution, a combination of implementation measures may be required to reduce nutrients and algae to acceptable levels. The following discussion presents several potential implementation strategies that could be used to comply with the TMDL and their associated costs.

The cost estimates for the potential implementation actions are intended to provide the Regional Board with a reasonable range of potential costs of implementing this TMDL. The cost estimates are not additive; rather, responsible parties may implement individual potential treatment alternatives or a combination of alternatives and the costs would vary accordingly. The cost estimates account for a range of economic factors and require a number of assumptions regarding the extent of implementing many of the measures. In reviewing the cost estimates, it should be noted that there are multiple additional benefits associated with the implementation of these strategies. Many of the structural and non-structural BMPs to address nutrient loadings could also reduce the loading of other contaminants, which could assist in meeting the requirements of other existing or future Ventura River TMDLs.

7.3.1 Waste Water Treatment Plant Upgrades

7.3.1.1 Upgrading Nitrification-Denitrification (NDN) Processes at Ojai Valley WWTP

The Ojai Valley WWTP currently operates with advance secondary treatment including nitrification and denitrification. Three alternatives have been previously considered by the Ojai Valley Sanitation District to upgrade the WWTP in order to decrease nutrient discharges (MWH, 2007). The first two options consider a total nitrogen limit of 3mg/L, and a phosphorus limit of 1mg/L. The third scenario considers a total nitrogen limit of 1mg/L and a phosphorus limit of 0.1mg /L. The first two alternatives are presented here based on the WLAs for the Ojai WWTP equal to 3 mg/L TN and 1 mg/L TP.

7.3.1.2 Conversion to Modified Bardenpho process

The first alternative to improve the plant's denitrification capacity is to convert the existing three stage process (comprised of successive anaerobic, anoxic and anaerobic zones) to a five-stage Modified Bardenpho process. The upgrade consists of the addition to the existing process of a second (post-aeration) anoxic zone, including inclusions of carbon in the form of methanol to increase denitrification, followed by a third aerobic zone. The

capital cost for this option is estimated to be 16.6 million dollars, with operation and maintenance costs of $205,000 annually (adjusted to 2012 dollars).

7.3.1.3 Addition of denitrification filters

The second proposed implementation alternative is the addiction of denitrification filters to the existing facilities, a process that serves the dual purpose of denitrification and filtration of suspended solids. The heterotrophic microorganisms cultivated on the Granular media denitrification filters will require methanol addition as a source of carbon to sustain growth. The estimated construction cost is 17.2 million dollars and the maintenance cost is $270,000 per year (adjusted to 2012 dollars).

With either of these alternatives optimization of phosphorus removal can be added. Based on the MWH (2007) report the facility has capabilities to include alum or other coagulant treatments.

7.3.2 Urban Runoff Implementation Alternatives

7.3.2.1 Biofilter systems

Biofilters, also known as vegetated swales and filter strips, are vegetated slopes and channels designed and maintained to transport runoff slowly over vegetation. The slow movement of runoff through the vegetation provides an opportunity for sediments and particulates to be filtered and degraded through biological activity. In most soils, the biofilter also provides an opportunity for infiltration of dry-weather runoff and storm water, which further removes nutrients and reduces runoff volumes. Swales convey flows to a vegetation-lined channel and grass filter strips intercept sheet runoff to a uniformly graded buffer zone. Grass strips and vegetated swales can function as pretreatment systems for water entering bioretention systems or other BMPs. These can be installed as on-site features of developments or in street medians, parking lot islands, or curb extensions (CASQA, 2003). Biofilters can be used to effectively reduce nutrient loading; the range of removal efficiency is 20 – 80 percent (CASQA, 2003).

Vegetated swales or filter strips, based on case studies, are capable of managing runoff from small drainage areas with approximate sizes of 10 acres. Considering a unit swale that is 10 feet wide and 1,000 feet long, which results in a hydraulic residence time of at least 10 minutes, for each 10 acres of drainage area, the ratio of the swale surface area to each draining acre, is 1,000 square feet per acre (CASQA, 2003). The mid-range cost to construct a swale for treatment of a 10-acre drainage area is $20,000 (adjusted to 2012 dollars) (CASQA, 2003). The annual maintenance cost is estimated at 5% (Table 7-2).

Table 7-2 Summary of vegetated swales costs

Items	Unit Cost (per 10-acre drainage area)
Capital Cost	$20,000
Operation and Maintenance Cost	$100

7.3.2.2 Alum Injection Systems to treat urban runoff

Alum injection systems are another treatment option for dry weather or stormwater runoff. Alum injection is the process of adding aluminum sulfate salt (alum), to stormwater prior to discharge into the river. The systems can be installed and sited at appropriate locations in the watershed. Alum fixes itself to common pollutants, such as phosphorus, and the floc settles from the water column. Studies of the effectiveness of nutrient removal report 30 - 90 percent removal for nitrogen and phosphorus.

Parameters to be considered for design of the automated alum injection system include the stormwater drainage area, flow rate of stormwater discharge, locations of the system, and the seasonal precipitation. The construction cost for a drainage area of 1,500 acres ranges from $100,000 to $550,000 with the average capital cost of $2,100 per acre treated (adjusted to 2012 dollars). The overall operation and maintenance cost ranges from $37 to $287 per acre treated per year, with an average of $166 dollars per acre per year (Harper, Herr, Livingston, 1999) (Table 7-3).

Table 7-3 Summary of alum injection costs

Items	Unit Cost
Capital Cost	$2,100 per acre
Operation and Maintenance Cost	$166 per acre per year

7.3.2.3 Constructed wetlands

Constructed treatment wetlands are designed to maximize the removal of pollutants from storm water and dry-weather urban runoff through settling and uptake and filtering by vegetation. Constructed wetlands temporarily store runoff in a shallow marsh that support conditions suitable for the growth of wetland plants. These excess nutrients are absorbed by wetland soils and taken up by plants and microorganisms. The treatment efficiency of constructed wetlands varies considerably (TN 26% $\pm$ 49%, TP 43% $\pm$ 40%); however, proper design and maintenance helps to improve their performance (US EPA, 2003a).

CASQA (2003) reports an estimated cost of wetland installation for a 100 acre-foot facility of $1,800,000 (adjusted to 2012 dollars). Annual operation and maintenance costs are estimated at 5% of the construction cost (Table 7-4).

Table 7-4 Summary of storm water constructed wetland costs

Items	Unit Cost
Capital Cost	$18,000 per acre
Operation and Maintenance Cost	$900 per acre per year

7.3.2.4 Non-structural BMPs

Non-structural BMPs include educational and pollution prevention practices. Several nonstructural BMPs are listed below.

- Prohibition of non-stormwater discharges to the MS4
- Increased cleaning of catch basin inlets and open channels
- Public education and outreach
- Illicit connection and discharge prevention

The costs for a number of non-structural measures have been estimated for the entire Los Angeles Region (Devinny et al., 2004), which has an area of 3,100 square miles. The source control measure costs for the Ventura River watershed were scaled down proportionally. The Ventura River watershed is approximately 228 square miles. The watershed has 17.9 square miles of urban area that could need to be treated to comply with the TMDL. The following represent the approximate values for the Ventura River watershed for source control measures based on the Devinney et al., study:

- Public education - $28,871 per year
- Increased storm drain cleaning - $155,903 per year

The prohibition of non-stormwater discharges and the illicit connection elimination programs are existing MS4 programs and the costs were not estimated.

7.3.3 Agriculture Implementation Alternatives

7.3.3.1 Filter Strips

NRCS estimates that filter strips planted with native plant material are $1,031 per acre of filter strip installed. Staff estimated a ratio of treated agricultural land area to filter strip area of 60:1 using design methods described in *Design of Stormwater Filtering Systems* (CWP, 1996) and assuming a 99% pervious drainage area, a 1-inch storm, a minimum filter strip length of 25 feet, a berm height of six inches, and a 150-foot by 150-foot drainage area.

The calculated 60:1 ratio is consistent with the NRCS Conservation Practice Standard for Filter Strips (Code 393), which specifies that the ratio of the drainage area to filter strip area shall be less than 60:1 in regions with RUSLE-R (Revised Universal Soil Loss Equation- Rainfall-Erosivity) factor values of 35-175 (RUSLE-R factor values for California range from 60-100).

Assuming a ratio of treated agricultural land area to filter strip area of 60:1, the cost of filter strips is $17 per acre of agricultural land treated. According to Code 393, filter strips should be designed to have a 10-year lifespan. Assuming a 10-year lifespan and a 5 percent discount rate, the equivalent annual cost of filter strips is $2 per acre-year.

7.3.3.2 Mulching

NRCS estimates that mulching costs $808 per acre of mulch applied. The NRCS Conservation Practice Standard for Mulching (Code 484) specifies that mulching should be applied at a rate to achieve a minimum of 70 percent ground cover to provide erosion control. Therefore, the cost of mulching is $566 per acre of agricultural land treated.

According to the NRCS Field Office Technical Guide (FOTG) for mulching, the reported lifespan for this practice is one year, but local NRCS staff has reported that woody mulch can last two to three years and mulch residue can last up to five years. Assuming a lifespan of three years and a 5% discount rate, the equivalent annual cost of mulching is $208 per acre-year.

7.3.3.3 Improved Irrigation Efficiency and Nutrient Management

Often replacing a traditional irrigation system with a drip irrigation system can reduce nutrient runoff. Improved maintenance of the systems may further reduce farm runoff. Costs for installing and maintaining micro-irrigation systems vary according to the type of production found in the watershed (NRCS FOTG Cost Data 2010; see Table 7-5 below). On average, the installation cost is $1784 per acre, with a maintenance cost of $84.

Table 7-5 Summary of micro-irrigation costs

Items	Unit Cost
Nursery or greenhouse	
Capital Cost	$3,006 per acre
Operation and Maintenance Cost	$150 per acre per year
Lifespan	10 years
Orchard or vineyard > 10 acres	
Capital Cost	$1406 per acre
Operation and Maintenance Cost	$70 per acre per year
Orchard or vineyard < 10 acres	
Capital Cost	$2006 per acre
Operation and Maintenance Cost	$100 per acre per year
Row/field cropland. Buried manifold	
Capital Cost	$1506 per acre
Operation and Maintenance Cost	$75 per acre per year
Row/field cropland. Layflat manifold	
Capital Cost	$996 per acre
Operation and Maintenance Cost	$50 per acre per year
AVERAGE	
Capital Cost	$1784 per acre
Operation and Maintenance Cost	$89 per acre per year

The NRCS cost estimate for a nutrient management plan is $55 per acre-year (NRCS FOTG Cost Data, 2010).

7.3.3.4 Manure Management

Manure management requires horses and/or livestock owners to collect, store, and dispose of manure in a manner that minimizes nutrient contributions to the river. One method to properly store manure is to construct manure bunkers that prevent stormwater and dry-weather runoff from carrying nutrients to the river. The average cost to construct a manure bunker is $4,500 (Ecology Action, personal communication, in CRWQCB 2009; adjusted to 2012 dollars). This cost applies to bunkers constructed on an existing cement slab, or a where a new one was poured, and includes a permanent roof or a tarp cover. The cost of bunkers varies depending on the size and materials, and ranges from $3000 to $17,000.

7.3.3.5 Grazing Management

Grazing management protects stream banks, riparian zones, and minimizes nutrient contributions to the river and tributaries. Grazing management includes using fencing, stream crossings, and providing alternative drinking locations in order to exclude livestock from sensitive areas. Grazing management can also reduce upland erosion through prescribed grazing, seeding, and gully erosion control which utilizes grade stabilization and ponds. Federal land managers (i.e. Bureau of Land Management, Forest Service) have plans with recommendations for grazing management practices (US EPA, 2003b).

Preventing horses and cattle access to waterways requires the installation of fences along portions of streams susceptible to damage and installation of watering facilities to provide

an alternative water source for the animals. An average installation cost of fencing is $7.6 per feet. The costs range depending on the type of fencing from $2.20 – $13 (Table 7-6).

Table 7-6 Summary of fencing costs

Items	Unit Cost
Conventional*	
Capital Cost	$13 per feet
Operation and Maintenance Cost	$0.2 per feet per year
Electric	
Capital Cost	$2.2 per feet
Operation and Maintenance Cost	$0.1 per feet per year
Woven wire*	
Capital Cost	$13 per feet
Operation and Maintenance Cost	$0.2 per feet per year
AVERAGE	
Capital Cost	$6.1 per feet
Operation and Maintenance Cost	$0.1 per feet per year

* Based on the difficulty of the terrain in the Ventura River watershed, numbers for conventional and woven wire fences are for structures built on very rugged, undulating sites with heavy brush and/or with stony, shallow or sand soils. Such evaluation was not available for the cost of electric fencing.

The demand for alternative water facilities is related to the size of the ranching operation; unit cost for watering facilities varies based on volume (Table 7-7). The average cost of a typical watering facility is $1,356.

Table 7-7 Summary of watering facilities costs

Items	Unit Cost
2,501-5,000 gal	
Capital Cost	$2,413 per unit
Operation and Maintenance Cost	$46 per unit per year
601-2,500 gal	
Capital Cost	$1529 per unit
Operation and Maintenance Cost	$30 per unit per year
300-600 gal	
Capital Cost	$991 per unit
Operation and Maintenance Cost	$13 per acre per year
<300 gal	
Capital Cost	$491 per unit
Operation and Maintenance Cost	$9 per unit per year
AVERAGE	
Capital Cost	$1356 per unit
Operation and Maintenance Cost	$25 per unit per year

7.3.4 Anaerobic Biodigester Systems

Manure produced by horses and livestock can be converted to biogas for renewable source of energy. The biodigester mixes organic wastes and manure with water and bacteria. During anaerobic digestion, bacteria break down organic wastes and manure in an oxygen-free environment.

The Waste to Energy project team is proposing to build an anaerobic digester in the Ojai Valley (W2E) to convert organic wastes produced in the area to energy (electricity/biogas), compost, and liquid fertilizer (W2E, 2010). The solid organic wastes in the Ojai Valley are estimated to be 30-70 tons/day; the proposed biodigester, with a capacity of 50-75 tons/day, could potentially treat the majority this waste. The estimated construction costs for the plant are 6 to 8 million dollars (W2E, 2010) and subsequent annual costs for a 50 tons/day plant (scaled up from the 31 tons/day biodigester at UC Davis) are estimated to be about $420,000 annually. Annual revenues could total $725,000 per year based solely on sale of power. Accordingly, the payback period for the capital would be 5 to 10 years (Table 7-8). A feasibility study is to be completed by a grant administered by the Ventura County Watershed Protection District in 2012 and should be used for further planning.

Table 7-8 Summary of anaerobic biodigester systems costs

Items	Total Cost
Capital Cost	$6,000,000 to $8,000,000
Operation and Maintenance Cost	$420,000 annually
Revenue	$725,000 annually

7.3.5 OWTS Inspections and Upgrades

Various actions may be required to reduce the loading from OWTS. These may include actions ranging from inspection or regular monitoring to the installation of supplemental treatment. An assessment of a site to determine if a particular OWTS is contributing to surface water loading of nutrients could cost as much as $5,000 dollars. The Regional Board will work with local agencies to utilize existing monitoring wells and data to the extent practicable in order to reduce costs. If testing confirms the need for advanced treatment, the cost of upgraded systems could cost up to $22,000 dollars (SWRCB, 2012). There would also be ongoing maintenance and monitoring requirements to ensure the advanced treatment is performing well.

The cost of compliance for OWTS owners will depend on the type of system and the capacity of the system. Local agencies will likely incur additional costs to the extent that they need to revise their existing programs or practices. These local agency costs may be passed on to OWTS owners in the form of permit fees.

The relatively high costs of supplemental treatment OWTS may make the option of connecting to the community collection system attractive to members of a neighborhood or community where local siting conditions are challenging or not appropriate for individual systems. Connection fees are approximately $15,000 per connection. There are additional

costs with demolishing the existing OWTS and updating the site pluming to accommodate the sewer connection, which can cost approximately $10,000 per unit. (Jeff Palmer, personal communication, June 16, 2012.)

The SWRCB has set aside funds from its State Revolving Fund Program that can be made available to local qualified agencies who can then provide low-interest loans to homeowners to repair, replace, or upgrade their OWTS or connect to the sewer system.

7.3.6 Watershed Wide Implementation

7.3.6.1 Riparian Buffers and Stream Bank Stabilization

Riparian buffers consist of an area of trees, usually accompanied by grasses, shrubs, and other vegetation that are adjacent to a waterbody. They reduce the impact of nonpoint source pollution by trapping and filtering sediments, nutrients, and other chemicals from surface runoff and shallow groundwater. The leaf canopy provides shade that keeps the water cool, discouraging algae growth and thus retaining more dissolved oxygen. Trees and shrubs near the waterway stabilize the bank, improve and protect the aquatic environment, and protect stream banks from flood erosion and debris damage. Riparian enhancements may include a wide variety of practices intended to restore the natural condition and function of the river and its riparian area. These practices may include stream bank stabilization and outfall protection, planting of stream bank vegetation and establishment of sufficient stream buffers, removal of invasive plant species, improvement of floodplain connections, removal of fish barriers, and enhancement of wetlands (OCES, 1998).

7.3.7 Matilija Dam Removal

In order to restore ecological function of the Ventura River, removal of Matilija Dam and accumulated sediments behind the dam is planned. A final EIS/EIR was completed in 2004, which identified the preferred dam removal alternative. In the preferred alternative, the entire concrete dam structure above the original streambed will be removed; sediments will be slurried in pipelines to downstream sediment placement sites. This alternative is estimated to take three years to complete.

Slurry disposal site will be within the River's floodplain and the sediments may erode in storm events and contribute to winter nutrient loading. Potential slurry disposal sites are below the Robles Diversion. The sediments from the slurry disposal sites will be protected from erosion up to a 10-year storm.

Prior to the issuance of a Clean Water Act Section 401 Water Quality Certification from the Regional Board for the dam removal project, the project proponents will be required to develop an estimate of the potential for nutrient contributions from the stored sediments during storms and the appropriate level of sediment protection that will be required such that sediments do not cause or contribute to nutrient impairments addressed by this TMDL.

7.4 Monitoring Program

The monitoring programs will be designed to measure improvement in water quality and pollutant load reductions. The monitoring program has several goals including:

- Determine attainment of numeric targets;
- Determine compliance with the waste load and load allocations;
- Monitor the effect of implementation actions on river and estuary water quality.

The TMDL monitoring program will consists of three components 1) receiving water monitoring, 2) discharger monitoring, and 3) optional special studies. All monitoring requirements may be included in subsequent permits or other orders and are subject to Executive Officer approval.

7.4.1 Receiving Water Monitoring

Responsible parties (OVSD, Ventura County Watershed Protection District, Ventura County, the City of Ojai, the City of Ventura, Caltrans, and agricultural dischargers) are responsible for developing and implementing a comprehensive monitoring plan to assess numeric target attainment and measure in-stream nutrient concentrations. Responsible parties are encouraged to work together to submit a join watershed-wide plan. Once horse and livestock owners are enrolled in the regulatory mechanism to implement their LAs, they shall participate in the implementation of the watershed-wide monitoring plan or submit their own plan. The monitoring plan should outline a program to sample for algal biomass, algal percent cover, nutrients (total and dissolved), *in situ* water quality parameters (dissolved oxygen, pH, temperature, electrical conductivity), and flow for the river and estuary. Monitoring should include visual observations documenting whether the Estuary is open or closed. The monitoring procedures/methods, analysis, and quality assurance shall be SWAMP comparable where appropriate. The sampling frequency and locations must be adequate to assess beneficial use condition and attainment of applicable water quality objectives. At a minimum, for algal biomass and percent cover, the monitoring frequency shall be once per month in the dry season (May 1st to September 30th). After two years, if a significant difference between monthly algal biomass measurements is not observed, algal biomass monitoring may be reduced to three times per dry season, during the months of May, July, and September. DO and pH shall be measured continuously for two week periods on a quarterly basis. Continuous monitoring of DO and pH shall occur during the months of May and September in the 2nd and 3rd quarters. All other parameters shall be monitored monthly.

Existing receiving water monitoring conducted under other programs can be leveraged to assist in meeting these monitoring requirements. Responsible parties may build upon existing monitoring programs in the Ventura River watershed when developing the receiving water quality monitoring plan for this TMDL. Receiving water monitoring requirements shall be incorporated into the regulatory mechanisms for each responsible party upon issuance, renewal, or modification. The responsible parties may continue to coordinate a watershed-wide monitoring program to meet this requirement in order to

fulfill permit, WDR, or waiver requirements. Receiving water monitoring shall continue beyond the final implementation date of the TMDL unless the Executive Officer approves a reduction or elimination of such monitoring.

7.4.2 Discharge Monitoring

Discharge monitoring will assess attainment of the waste load and load allocations. Dischargee monitoring shall be required through the regulatory mechanisms used to implement the waste load and load allocations. Discharge monitoring shall be conducted at the frequency specified in Section 7.1 of the TMDL. The monitoring procedures/methods, analysis, and quality assurance shall be SWAMP comparable where appropriate.

7.4.3 Special Studies

Responsible parties within the watershed may conduct optional special studies designed to refine waste load and load allocations and numeric targets. The results of special studies and monitoring may be used to revise numeric targets and allocations, if supported, when the TMDL is reconsidered. The following are potential special studies.

- Build upon the algal biomass and total nitrogen relationship established in the 2008 UCSB Study (UCSB, 2009) and collect data to support the establishment of reach-specific relationships.
- Confirm the conclusion that an algal biomass target of 150 mg/m^2 is fully protective of aquatic life and minimizes the risk of low DO events.
- Collect additional source assessment information and model input data to refine model predicted relationships between watershed loading and in-stream nutrient concentrations.
- Investigate the influence of OWTS on surface water quality.
- Collect data to support development of an estuary model, which takes into account tidal influence, the dynamics of macroalgae and phytoplankton growth, residence time, and breaching conditions.

7.5 Implementation Schedule

The proposed implementation schedule shall consist of a phased approach consisting of monitoring and special studies before allocations become effective as presented in Table 7-9. The schedule allows six to 10 years from the effective date to meet the dry-weather and wet-weather load and waste load allocations in Ventura River and its tributaries.

Table 7-9 Implementation Schedule

Task	Due Date
Submit results of optional special studies.	4 years after effective date of TMDL
Reconsider TMDL to revise numeric targets and allocations if supported by special studies or other changes in the watershed.	5 years after effective date of TMDL
OVSD	
Wet-weather and interim dry-weather WLAs apply	Effective date of TMDL
Submit receiving water monitoring plan to assess numeric target attainment and measure in-stream nutrient concentrations	1 year after effective date of TMDL
Initiate receiving water monitoring plan	90 days after approval of receiving water monitoring plan
Compliance monitoring plan incorporated into permit	Upon permit adoption, renewal, or modification
Dry-weather WLA apply	No later than 10 years after effective date of TMDL*
Ventura County MS4 Permitees and Caltrans	
Wet-weather WLAs apply	Effective date of TMDL
Discharge monitoring plan incorporated into permit	Upon permit adoption, renewal, or modification
Submit receiving water monitoring plan to assess numeric target attainment and measure in-stream nutrient concentrations.	1 year after effective date of TMDL
Initiate receiving water monitoring plan	90 days after approval of receiving water monitoring plan
Submit implementation plan to achieve compliance with the WLAs. The plan shall include implementation methods, an implementation schedule, proposed interim milestones, and compliance points.	2 years after effective date of TMDL
Dry-weather WLAs apply	6 years after effective date of TMDL
General Industrial and Construction Stormwater Permittees	
Wet-weather and dry-weather WLAs apply	Effective date of TMDL
Discharge monitoring plan incorporated into permit	Upon permit adoption, renewal, or modification
Other NPDES Permitees	
Wet-weather and dry-weather WLAs apply.	Effective date of TMDL
Discharge monitoring plan incorporated into permit.	Upon permit adoption, renewal, or modification
Agricultural Discharges	
Discharge monitoring plan incorporated into Agriculture Waiver or other order	Upon adoption, renewal, or modification
Submit receiving water monitoring plan to assess numeric target attainment and measure in-stream nutrient concentrations	1 year after effective date of TMDL
Initiate receiving water monitoring plan	90 days after approval of receiving water monitoring plan

Task	Due Date
Wet-weather and dry-weather WLAs apply	6 years after effective date of TMDL
Onsite Waste Water Treatment Systems	
Wet-weather and dry-weather WLAs apply	10 years after effective date of TMDL
Horse/Livestock Owners	
Discharge monitoring plan submitted as part of waiver requirement or in response to Regional Board order	5 years after effective date of TMDL
Join watershed-wide group to conduct receiving water monitoring to assess numeric target attainment and measure in-stream nutrient concentrations or submit own plan	5 years after effective date of TMDL
Wet-weather and dry-weather WLAs apply	10 years after effective date of the TMDL

*If TMDL reconsideration results in more stringent WLAs, then the implementation schedule for OVSD may be extended, if necessary, by only the amount of time required to upgrade treatment processes to meet the more stringent WLAs.

Secondary Drinking Water Standards

California Code of Regulations, Title 22
Division 4. Environmental Health
Chapter 15. Domestic Water Quality and Monitoring Regulations
Article 16. Secondary Drinking Water Standards

Constituents	Maximum Contaminant Levels Consumer Acceptance Contaminant Levels
Aluminum	0.2 mg/L
Color	15 Units
Copper	1.0 mg/L
Foaming Agents [MBAS]	0.5 mg/L
Iron	0.3 mg/L
Manganese	0.05 mg/L
Methyl-*tert*-butyl ether [MTBE]	0.005 mg/L
Odor---Threshold	3 Units
Silver	0.1 mg/L
Thiobencarb	0.001 mg/L
Turbidity	5 Units
Zinc	5.0 mg/L

Maximum Contaminant Levels
Consumer Acceptance Contaminant Levels Ranges

Constituents	Recommended	Upper	Short Term
Total Dissolved Solids [TDS]	500 mg/L	1,000 mg/L	1,500 mg/L
Specific Conductance	900 µS/cm	1,600 µS/cm	2,200 µS/cm
Chloride	250 mg/L	500 mg/L	600 mg/L
Sulfate	250 mg/L	500 mg/L	600 mg/L

Note: There are no public health goals (PHGs) or maximum contaminant level goals (MCLGs) for these constituents because secondary standards are set on the basis of aesthetic concerns.

The State Water Resources Control Board (State Water Board) and the nine Regional Water Quality Control Boards (Regional Water Boards), collectively known as the California Water Boards (Water Boards), are dedicated to a single vision: abundant clean water for human uses and environmental protection to sustain California's future. Under the federal Clean Water Act (CWA) and the state's pioneering Porter-Cologne Water Quality Control Act, the State and Regional Water Boards have regulatory responsibility for protecting the water quality of nearly 1.6 million acres of lakes, 1.3 million acres of bays and estuaries, 211,000 miles of rivers and streams, and about 1,100 miles of exquisite California coastline.

Water Boards or Water Resources?

The State Water Resources Control Board (State Water Board) and the nine Regional Water Quality Control Boards (Regional Boards) protects water quality and allocates surface water rights.

The Department of Water Resources is responsible for the management of water usage including the delivery of water to two-thirds of California's population through the State Water Project.

VENTURA RIVER 1 LEVEE SYSTEM

VENTURA COUNTY, CALIFORNIA
NLD ID # 380510086

PERIODIC INSPECTION REPORT NO 1
GENERALIZED EXECUTIVE SUMMARY
8 JUNE 2012

FINAL RATING: MINIMALLY ACCEPTABLE
FINAL RATING DATE: 13 MARCH 2012

PERIODIC INSPECTION REPORT PREPARED BY: FUGRO WEST, INC.
SUBMITTED: JUNE 2011
INSPECTED: 25-26 MAY 2010

EXECUTIVE SUMMARY

This Executive Summary provides an introduction to the periodic inspection, an overview of the system, a summary of the major findings of the periodic inspection, and the overall rating for the system.

1.1 SCOPE AND PURPOSE OF PERIODIC INSPECTION

Fugro has been authorized by the U.S. Army Corps of Engineers (USACE/Corps), Los Angeles District (L.A. District) to perform a Periodic Inspection (PI) of the Ventura River 1 Levee System (VR-1) in Ventura County, California. The purpose of the PI is to verify proper operation and maintenance, evaluate operational adequacy and structural stability, review design criteria to identify changes in current design standards, identify features to monitor over time, and improve the ability to communicate the overall condition. Levee certification is not part of this scope of work. The project is being funded under the American Reinvestment and Recovery Act.

1.2 SYSTEM SUMMARY

VR-1 is the reach of the Ventura River Levee system that has been designated by the Corps for PI, and consists of an approximate 2.65-mile-long stone-revetted left (east) bank levee that extends from the Pacific Ocean (Station 10+95) to the intersection with Canada de San Joaquin, where it continues approximately 1,100 feet along the left (south) bank of Canada de San Joaquin (Station 150+57). VR-1 provides flood control for the western portion of the City of San Buenaventura (Ventura) and adjacent areas along the Ventura River in Ventura County, California. Construction of the levee was completed by the Corps' L.A. District in December 1948. Other system features include: 15 culverts and side-drainage structures; the Southern Pacific Railroad (SPRR) Main Line Bridge crossing; the U.S. Highway 101 crossing; State Route 33 and Main Street crossings; the Stop-log Closure Structure at the SPRR (Ojai Branch) crossing; and Floodwalls #1 and #2. The Ventura County Watershed Protection District, or VCWPD (County), formerly known as the Ventura County Flood Control District (VCFCD), is the local agency responsible for the operation and maintenance of the levee. Figure 1 shows the location of VR-1.

1.3 SUMMARY OF MAJOR DEFICIENCIES FOUND

The VR-1 field inspection was conducted on May 25 and May 26, 2010. Several system deficiencies were observed and documented during the field inspection. Some of the primary deficiencies observed include the following:

1.3.1 Levee Embankments:

- Significant vegetation growth, particularly trees and bushes greater than 2 inches in diameter, was observed on both the riverward and landward sides of the levee within the vegetation-free zone. The vegetation threatens the operation and integrity of the levee.
- Several unpermitted encroachments were observed within the easement areas that are likely to negatively impact the integrity of the levee. Encroachments that will require permitting include seven non-Corps built culverts and side-drainage

structures, Floodwalls #1 and #2, the U.S. Highway 101 and State Route 33 crossings, an industrial development at the final upstream 200 feet of the levee, concrete k-rails, and utilities.

- Erosion zones were observed on both the riverward and landward side levee slopes, and the levee integrity may be threatened. Erosion zones consist of undercutting of the revetment and deterioration of access ramps on the riverward side.
- Areas of minor to significant riprap displacement and stone degradation were observed along the levee, and may pose a threat to the integrity of the levee in the event of a flood. For example, there was no riprap observed along the entire riverward side of multiple access ramps. Localized areas were observed along the levee where the riprap has degraded or deteriorated into 2- to 12-inch fragments. Other areas of displacement appear to be the result of human interference where the stone has been moved for the purpose of creating levee access locations.

1.3.2 Floodwalls:

- Floodwalls not shown on as-built plans that will require permitting include the approximate 550-foot-long Floodwall #1 and approximate 1,050-foot-long Floodwall #2.
- Active erosion and scouring were observed beneath Floodwall #1 during the field inspection, which may lead to structural instabilities before the next inspection.

1.3.3 Interior Drainage System

- A total of eight Corps-built and seven non-Corps-built, unpermitted culverts and side-drainage structures were observed during the field inspection. The County has provided as-builts plans for one culvert. Information regarding design and construction of the remaining six unpermitted culverts and side-drainage structures was not included in the documents reviewed.
- Several of the side-drainage structures contain debris and heavy sediment that has impaired the channel flow capacity and has blocked more than 10 percent of the culvert opening at the outfalls.
- A dirt access road, slurry sack headwalls and under-drains are unpermitted encroachments between the side-drainage structures and the riverbed. While these unpermitted features may enhance operations, maintenance, and emergency access within the riverbed, in some cases they appear to inhibit adequate drainage from the structures.
- Unpermitted 3-foot-long x 2-foot-wide catch basins with metal grates were observed within 15 feet of the landward side toe across from four side-drainage structure outfalls. We could not confirm in the field whether or not those catch basins are modified inlets at ponding areas for the side-drainage structures. The size and capacity of each catch basin is unknown.
- Significant damage and obstructions were observed at the outlet of the Abandoned 30-inch CMP Drain. In addition, information regarding the interior condition of the pipes (via video camera or visual inspection methods) was not provided.

- The slide gate at the inlet for the Abandoned 30-inch CMP Drain is heavily corroded and inoperable.

1.4 OVERALL SYSTEM RATING

The final rating for the system is “Minimally Acceptable”.

A Minimally Acceptable System is where one or more items are rated as Minimally Acceptable or one or more items are rated as Unacceptable and an engineering determination concludes that the Unacceptable items would not prevent the segment/system from performing as intended during the next flood event.

This levee system inspection was based on observations of field conditions and available data at the time of the inspection. The condition of any levee system depends on numerous and constantly changing internal and external conditions and is evolutionary in nature. It is incorrect to assume the present condition of the levee system will continue to represent the condition of the levee system in the future. Only through continued inspection, maintenance, repair, and rehabilitation can there be a reasonable chance that unsafe conditions can be avoided.

Executive Summary

The purpose of this report is to provide a summary of Calendar Year 2015 water quality and groundwater elevation conditions, and to highlight other significant activities. This report is written with a broad target audience in mind from residents to consultants and other professionals. The report presents information and data from a broad perspective and with greater detail for the groundwater basins. Basin summary sheets have been prepared for the second year and are included after this Executive Summary. These basin summary sheets include analysis of water level and water quality trends over a five year period as well as data regarding basin size, number and types of wells, amount of irrigated agriculture, and other key data. Subsequent report sections present more specific water level and water quality data for each of the studied basins, and finally appendices contain specific data used in the report.

Calendar year 2015 is the fourth consecutive year of below average rainfall in the County which is currently designated as an area of exceptional drought by the U.S. Drought Monitor (http://droughtmonitor.unl.edu/). The drought and regulatory constraints on surface water releases and diversions from Lake Piru have caused a decrease in Santa Clara River water diversions. As less surface water is available, groundwater demand increases locally. Groundwater elevations in most areas of the County have continued the declining trend from last year. Water quality samples from 221 wells were collected between August and December of 2015. Twenty eight of the wells sampled had nitrate (NO_3) concentrations above the State of California Maximum Contaminant Level (MCL) of 45 mg/l. Water quality trends within basins are generally unchanged from previous years, with varying trends among individual wells. Key water quality concerns in some basins continue to be high total dissolved solids (TDS), and nitrate exceeding the maximum contaminant level in localized areas.

Groundwater extraction in certain areas of the County is regulated by other agencies. In 2014, the Fox Canyon Groundwater Management Agency (FCGMA) set forth mandatory cut backs in groundwater extractions over an eighteen month period for municipal, industrial and agricultural users through adoption of Emergency Ordinance E. Emergency Ordinance E remains in effect until the drought conditions no longer exist and is currently at its maximum mandatory cut back requirement. On January 1, 2015, the Sustainable Groundwater Management Act (SGMA) became effective signaling a new era in groundwater management in California. As required under SGMA, all Bulletin 118 groundwater basins designated as high or medium priority and critically overdrafted, shall be managed by a groundwater sustainability plans (GSP) by January 31, 2020. Many of the basins underlying the County boundaries are designated as high or medium priority and three are critically overdrafted (Cuyama Valley Basin [DWR No. 3-13], Oxnard Basin [DWR No. 4-04.02] and Pleasant Valley Basin [DWR No. 4-06]). GSPs are currently being developed with the goal of achieving sustainable groundwater management of all basins within the County.

In 2014, the County updated Well Ordinance 4184 (now 4468) to reflect changes in new well construction and State Legislation. The County regulates groundwater well construction and destruction through its Well Ordinance, but does not regulate groundwater extraction. The purpose of Well Ordinance 4468 is to provide for protection of groundwater quality and supply by regulating the construction, maintenance, operation, use, repair, modification, and destruction of wells and engineering test holes (soil borings) in such a manner that the groundwater of the County will not be contaminated or polluted, and that water obtained from wells will be suitable for beneficial use and will not jeopardize the health, safety or welfare of the people of Ventura County.

Basin Summary Sheets

The following basin summary sheets provide an overview of data, trends, and facts for some of the larger groundwater basins in the County. Trends for groundwater levels were determined for 2015 and over the last five years. Trends for groundwater quality were determined for the last five year period. Trend analysis used sample sets with wells that were sampled or measured consistently over the five year period. In some instances this resulted in a small sample set. The spatial distribution of the wells may not cover the entire groundwater basin. Data from VCWPD and other agencies was used in the trend analysis.

Basin Summary Sheet Key

Groundwater Basin Surface Area: **Irrigated Acreage:** **Watershed:** **Aquifers:** **DWR Groundwater Basin Designation and Size:** **CASGEM Basin Priority:** **DWR Groundwater Basin Population:**	In this section you will find quick facts about the groundwater basin.
Known Water Supply Wells In this section you will find information about the number of wells, and other status, in the groundwater basin.	**Self Reported Groundwater Extraction / Extraction Estimate** In this section you will find information on groundwater extractions reported to an agency or an estimate of extractions if outside of an agency boundary.
Groundwater Levels in General for All Wells Gauged by County In this section you will find information about groundwater levels gauged by the County during the report year.	**Groundwater Quality in General for All Wells Sampled by County** In this section you will find information about groundwater quality for wells sampled by the County during the report year. Maximum Contaminant Level (MCL) is listed.
5 Year Groundwater Level Trend In this section you will find information about groundwater level trends over the last 5 year period for wells gauged by the County and other agencies.	**5 Year Groundwater Quality Trend 2011-2015** **SWN** **Nitrate** **Chloride** **TDS** **Sulfate** In this section you will find information about groundwater quality trends over the last 5 year period for wells sampled by the County and other agencies.
Sources of Groundwater Recharge This section describes sources of recharge to the groundwater basin.	**Subsurface Hydrologic Connection to Other Groundwater Basins** This section describes any known hydrologic connections between adjacent groundwater basins.
DWR CASGEM Groundwater Basin Prioritization Level - Medium This section provides any notable comments by DWR about groundwater basin concerns.	
Groundwater Quality Trend Notes: Trend is relatively flat, or no clear trend ; Level trending up ; Level Trending down	

Oxnard Plain Pressure Basin

Groundwater Basin Surface Area:	47,167 acres
Irrigated Acreage:	≈21,540 (estimate determined from Ventura County Ag Commissioner's data)
Watershed:	Santa Clara River and Calleguas Creek
Aquifers:	Unconfined and confined aquifers
DWR Groundwater Basin Designation and Size:	Santa Clara River Valley Basin, Oxnard Subbasin (4-4.02) Surface area 58,200 Acres. Note: DWR groups two County basins into Oxnard Subbasin (4-4.02) (DWR, 2014)
CASGEM Basin Priority:	High
DWR Groundwater Basin Population:	235,973 (2010)

Known Water Supply Wells (as of Feb. 2016)

Number of Wells: 895
Active: 371
Destroyed: 382
Abandoned: 57
Can't Locate: 85

Self Reported Groundwater Extraction to FCGMA (as of March 30, 2016)

Agricultural Extractions: 51,168 AF/Yr

Municipal, Industrial, and Domestic Extractions: 11,946 AF/Yr

Total: 63,114 AF/yr

2015 Groundwater Levels in General for All Wells Gauged by County

UAS "Key" well 01N21W07H01S - December level was down 6.51 feet from the January measurement.

LAS "Key" well 01N21W32K01S - December level was down 38.10 feet from the January measurement.

In general for all wells consistently measured in 2015 in the basin, water levels declined over the course of the year from the 1st quarter reading to the last quarter reading.

2015 Groundwater Quality in General for All Wells Sampled by County

(66 wells)

UAS - Oxnard Pressure basin groundwater: Oxnard aquifer samples are calcium sulfate type. Mugu aquifer samples are calcium sulfate type.

LAS - Oxnard Pressure basin groundwater: Hueneme aquifer samples are calcium sulfate type. Fox Canyon aquifer samples are sodium sulfate type.

Primary MCL Exceedances for Nitrate >45mg/l?	Yes, 2 wells
Secondary MCL Excedances for Chloride >250mg/l?	Yes, 4 wells
Secondary MCL Excedances for TDS >500mg/l?	Yes, 62 wells
Secondary MCL Excedances for Sulfate >250mg/l?	Yes, 50 wells

For upper system, one well is in the northwest, the remaining wells are in the northeast. For lower system the wells are generally in the center of the basin along a northeast to southwest line, and a small group in the southeast.

Sources of Groundwater Recharge

Basin Recharge:percolation of surface flow from the Santa Clara River, into the Oxnard Forebay; precipitation and floodwater from the Calleguas Creek drainage percolate into the unconfined gravels near Mugu Lagoon. Some underflow may come from the Las Posas and Pleasant Valley Basins on the east. Flow into and out of Mound basin dependent on water levels. (DWR,

Potable Water Sources

Groundwater from Oxnard Plain Pressure Basin via various purveyors. Groundwater from Oxnard Forebay basin via United Water system. Surface water from Santa Clara River via United Water System. Imported State Project water from Calleguas MWD to various water purveyors.

Subsurface Hydrologic Connection to Other Groundwater Basins

North: Oxnard Forebay basin, Mound basin

East/Northeast: Pleasant Valley basin, West Las Posas basin

DWR CASGEM Groundwater Basin Prioritization Level - High

Impact Comments: Saline intrusion, nitrates, pesticides, and PCBs have impacted some water wells per DWR Bulletin 118

Groundwater Quality Trend Notes: Trend is relatively flat, or no clear trend →; Level trending up ↑; Level Trending down ↓

Fillmore Basin

Groundwater Basin Surface Area:	24,392 acres
Irrigated Acreage:	≈12,230 acres (estimate determined from Ventura County Ag Commissioner's data)
Watershed:	Santa Clara River
Aquifers:	Unconfined Aquifer
DWR Groundwater Basin Designation and Size:	Santa Clara River Valley Basin, Fillmore Subbasin (4-4.05). Surface area 20,842 acres. (DWR, 2006)
CASGEM Basin Priority:	Medium
DWR Groundwater Basin Population:	16,417 (2010)

Known Water Supply Wells (as of Feb. 2016)

04N20W36D07S	↓	↑	→	→

One well is at the western end of the basin, the remaining wells are in the southeast.

Sources of Groundwater Recharge

Basin Recharge: Infiltration of precipitation. Subsurface flow from Piru basin. Surface flow percolation from Santa Clara River, Sespe Creek, and minor tributaries. (DWR, 2006) Imported State Project Water via Lake Piru release to Santa Clara River.

Subsurface Hydrologic Connection to Other Groundwater Basins

Upgradient: Yes, Piru groundwater basin.
Downgradient: Yes, Santa Paula groundwater basin.

DWR CASGEM Groundwater Basin Prioritization Level - Medium

Impact Comments: Many groundwater quality impairments in the basin; Nitrates problematic during dry periods; High TDS, etc. DWR Bulletin 118. REH - PubComm indicated WQ is localized and being managed

Groundwater Quality Trend Notes: Trend is relatively flat, or no clear trend →; Level trending up ↑; Level Trending down ↓

Santa Paula Basin

Groundwater Basin Surface Area:	21,100 acres
Irrigated Acreage:	≈9,100 acres (estimate determined from Ventura County Ag Commissioner's data)
Watershed:	Santa Clara River
Aquifers:	Unconfined Aquifer
DWR Groundwater Basin Designation and Size:	Santa Clara River Valley Basin, Santa Paula Subbasin (4-4.04) Surface area 22,899 Acres. (DWR, 2014)
CASGEM Basin Priority:	Medium
DWR Groundwater Basin Population:	46,816 (2010)

Known Water Supply Wells (as of Feb. 2016)

Number of Wells: 283
Active: 152
Destroyed: 75
Abandoned: 11
Can't Locate: 45

Self Reported Groundwater Extraction to UWCD (as of March 3, 2015)

Agricultural Extractions: 18,161 AF/Yr

Municipal Extractions: 3,741 AF/Yr

Total Extractions: 21,902 AF/Yr

2015 Groundwater Levels in General for All Wells Gauged by County

"Key" well 02N22W02C01S - December level was down 14.62 feet from the March measurement.

In general for 7 of the 9 wells measured in 2015 in the basin, water levels declined over the course of the year from the 1st quarter reading to the last quarter reading.

2015 Groundwater Quality in General for All Wells Sampled by County

(6 wells)

The water type for the 6 wells is calcium sulfate type.

Primary MCL Exceedances for Nitrate >45mg/l?	No
Secondary MCL Excedances for Chloride >250mg/l?	No
Secondary MCL Excedances for TDS >500mg/l?	Yes, 6 wells
Secondary MCL Excedances for Sulfate >250mg/l?	Yes, 6 wells

5 Year Groundwater Level Trend 2011 - 2015

"Key" well 02N22W02C01S: ↓

The 5 year trend based on 2011 through 2015 potentiometric surface maps is downward.

5 Year Groundwater Quality Trend 2011-2015

(Based on 3 wells sampled by other agencies)

SWN	Nitrate	Chloride	TDS	Sulfate
02N22W02K09S	→	→	→	→
03N21W15C06S	→	→	↑	↑
03N21W16A02S	↑	→	↑	→

Four wells are in the southwest and two are in the northeast portion of the basin.

Sources of Groundwater Recharge

Basin Recharge: Infiltration of precipitation. Subsurface flow from Fillmore basin. Surface flow percolation from Santa Clara River, and Santa Paula Creek (DWR, 2006) Imported State Project Water via Lake Piru release to Santa Clara River.

Potable Water Sources

Groundwater from Santa Paula Basin

Subsurface Hydrologic Connection to Other Groundwater Basins

Upgradient: Yes, Fillmore groundwater basin.
Downgradient: Yes, Mound and Oxnard Plain Forebay groundwater basins

DWR CASGEM Groundwater Basin Prioritization Level - Medium

Impact Comments: Nitrates can fluctuate significantly in the basin, and above MCL. Other inorganics present above MCL.TDS is known to be high.

Groundwater Quality Trend Notes: Trend is relatively flat, or no clear trend →; Level trending up ↑; Level Trending down ↓

Piru Basin

Groundwater Basin Surface Area:	10,656 acres
Irrigated Acreage:	≈5,600 (estimate determined from Ventura County Ag Commissioner's data)
Watershed:	Santa Clara River
Aquifers:	Unconfined Aquifer
DWR Groundwater Basin Designation and Size:	Santa Clara River Valley Basin, Piru Subbasin (4-4.06). Surface area 8,915 acres. (DWR, 2014)
CASGEM Basin Priority:	High
DWR Groundwater Basin Population:	2,666 (2010)

Known Water Supply Wells (as of Feb. 2016)

Number of Wells: 190
Active: 152
Destroyed: 19
Abandoned: 6
Can't Locate: 13

Self Reported Groundwater Extraction to UWCD (as of March 3, 2015)

Agricultural Extractions: 11,517 AF/Yr

Municipal Extractions: 515 AF/Yr

Total Extractions: 12,032 AF/Yr

2015 Groundwater Levels in General for All Wells Gauged by County

"Key" well 04N19W25C02S - December level was down 11.97 feet from the March measurement.

In general for 5 wells consistently measured in 2015 in the basin, water levels declined over the course of the year from the 1st quarter reading to the last quarter reading.

2015 Groundwater Quality in General for All Wells Sampled by County

(15 wells)

Piru basin groundwater is mainly calcium sulfate type.

Primary MCL Exceedances for Nitrate >45mg/l?	Yes, 2 wells
Secondary MCL Excedances for Chloride >250mg/l?	No
Secondary MCL Excedances for TDS >500mg/l?	Yes, 15 wells
Secondary MCL Excedances for Sulfate >250mg/l?	Yes, 15 wells

5 Year Groundwater Level Trend 2011 - 2015

"Key" well 04N19W25C02S: ↓

The 5 year trend based on 2011 through 2015 potentiometric surface maps is downward.

5 Year Groundwater Quality Trend 2011-2015

SWN	Nitrate	Chloride	TDS	Sulfate
04N18W30A03S	↓	↓	↑	↑
04N18W30J04S	↑	↑	↑	↑
04N19W26H01S	↓	↑	↓	↓
04N19W26J05S	↑	→	↓	↓
04N19W34J04S	↑	→	↓	↓

One well is in the southwest, the remaining wells are in the north central portion.

Sources of Groundwater Recharge

Basin Recharge: Infiltration of precipitation. Subsurface flow from East basin. Surface flow percolation from Santa Clara River, Piru Creek and Hopper Creek. (DWR, 2006) Imported State Project Water via Lake Piru release to Santa Clara River and percolation ponds.

Subsurface Hydrologic Connection to Other Groundwater Basins

Upgradient: Yes, East groundwater basin.
Downgradient: Yes, Fillmore groundwater basin.

DWR CASGEM Groundwater Basin Prioritization Level - High

DWR Impact Comments:GW Quality impacts: nitrates, storm runoff, leaking tanks, etc. (DWR Bulletin118). High Selenium and other inorganics, average TDS was 1450 mg/l (Ventura Co 2011 annual gw report)

Groundwater Quality Trend Notes: Trend is relatively flat, or no clear trend →; Level trending up ↑; Level Trending down ↓

Pleasant Valley Basin

Groundwater Basin Name:	Pleasant Valley
Groundwater Basin Surface Area:	20,267 acres
Irrigated Acreage:	≈7,980 (estimate determined from Ventura County Ag Commissioner's data)
Watershed:	Calleguas Creek
Aquifers:	Unconfined and confined aquifers
DWR Groundwater Basin Designation and Size:	Pleasant Valley Basin (4-6). Surface area 21,654 acres. (DWR, 2014)
CASGEM Basin Priority:	High
DWR Groundwater Basin Population:	69,392 (2010)

Known Water Supply Wells (as of Feb. 2016)

Number of Wells: 332
Active: 91
Destroyed: 171
Abandoned: 26
Can't Locate: 44

Self Reported Groundwater Extraction to FCGMA (as of March 30, 2016)

Agricultural Extractions: 14,772 AF/Yr

Municipal, Industrial, and Domestic Extractions: 4,792 AF/Yr

Total: 19,564 AF/yr

2015 Groundwater Levels in General for All Wells Gauged by County

"Key" well 01N21W03C01S - December level was down 41.88 feet from the January measurement.

In general for 13 wells measured in 2015 in the basin, water levels declined over the course of the year from the 1st quarter reading to the last quarter reading.

2015 Groundwater Quality in General for All Wells Sampled by County

(19 wells)

Pleasant Valley basin groundwater: 1 sample is sodium sulfate type, and 13 samples are are calcium sulfate type

Primary MCL Exceedances for Nitrate >45mg/l?	Yes, 2 wells
Secondary MCL Excedances for Chloride >250mg/l?	Yes, 3 wells
Secondary MCL Excedances for TDS >500mg/l?	Yes, 19 wells
Secondary MCL Excedances for Sulfate >250mg/l?	Yes, 14 wells

5 Year Groundwater Level Trend 2011 - 2015

"Key" well 01N21W03C01S: ↓

Upper System

The 5 year trend based on 2011 through 2015 potentiometric surface maps is downward.

Lower System

The 5 year trend based on 2011 through 2015 potentiometric surface maps is downward.

5 Year Groundwater Quality Trend 2011-2015

Upper System

SWN	Nitrate	Chloride	TDS	Sulfate
01N21W15H01S	→	↓	↓	↓

Lower System

SWN	Nitrate	Chloride	TDS	Sulfate
01N21W03K01S	↑	↑	→	↓
01N21W03R01S	↑	↓	→	↓
01N21W04K01S	→	↑	↑	↑
01N21W10G01S	→	↓	↓	→
01N21W15D02S	→	↓	↓	↓
02N21W34G01S	→	↑	→	→

One well is in the north central portion, the remaining are in the southwest.

Sources of Groundwater Recharge

Basin Recharge: dominantly from subsurface flow across the Springville fault zone. A modest amount of irrigation water and septic system effluent also contribute to basin recharge. (DWR, 2006)

Potable Water Sources

Groundwater from Pleasant Valley Basin, groundwater from Arroyo Santa Rosa basin via Camrosa Water District. Imported State Project water from Calleguas MWD to various water purveyors.

Subsurface Hydrologic Connection to Other Groundwater Basins

West: Yes, Oxnard Plain Pressure Basin.

East: No.

DWR CASGEM Groundwater Basin Prioritization Level - High

Impact Comments: PC - Discharge of poor quality GW from dewatering wells and effluent discharge from the wastewater treatment facility into the Arroyo Simi have led to rising water levels in the basin along with higher TDS and Chloride levels.

Groundwater Quality Trend Notes: Trend is relatively flat, or no clear trend →; Level trending up ↑; Level Trending down ↓

Mound Basin

Groundwater Basin Surface Area:	12,023 acres
Irrigated Acreage:	≈2,075 acres (estimate determined from Ventura County Ag Commissioner's data)
Watershed:	Santa Clara River
Aquifers:	Unconfined and confined aquifers
DWR Groundwater Basin Designation and Size:	Santa Clara River Valley Basin, Mound Subbasin (4-4.03) Surface area 14,846 Acres. (DWR, 2014)
CASGEM Basin Priority:	Medium
DWR Groundwater Basin Population:	77,886 (2010)

Known Water Supply Wells (as of Feb. 2016)

Number of Wells: 78
Active: 29
Destroyed: 35
Abandoned: 6
Can't Locate: 8

Self Reported Groundwater Extraction to UWCD (as of March 3, 2015)

Agricultural Extractions: 2,687 AF/Yr

Municipal Extractions: 3,303 AF/Yr

Total Extractions: 5,990 AF/Yr

2015 Groundwater Levels in General for All Wells Gauged by County

"Key" well 02N22W07M02S - December level was down 3.72 feet from the January measurement.

In general for 5 wells measured in 2015 in the basin, water levels declined in 3 wells and rose in 2 wells over the course of the year from the 1st quarter reading to the last quarter reading.

2015 Groundwater Quality in General for All Wells Sampled by County

(5 wells)

The water type in 4 wells are calcium sulfate type, 1 well is sodium sulfate type.

Primary MCL Exceedances for Nitrate >45mg/l?	No
Secondary MCL Excedances for Chloride >250mg/l?	No
Secondary MCL Excedances for TDS >500mg/l?	Yes, 5 wells
Secondary MCL Excedances for Sulfate >250mg/l?	Yes, 5 wells

5 Year Groundwater Level Trend 2011 - 2015

"Key" well 02N22W07M02S: ⇩

The 5 year trend based on 2011 through 2015 potentiometric surface maps is downward.

5 Year Groundwater Quality Trend 2011-2015

02N23W15J02S	⇨	⇧	⇨	⇧
02N23W15J03S	⇧	⇧	⇨	⇨

Wells are generally in the center of the basin along a east to west line.

Sources of Groundwater Recharge

Basin Recharge: Infiltration of precipitation. Subsurface flow from Santa Paula basin. Surface flow percolation from Santa Clara River and, percolation of direct precipitation into the San Pedro Formation which crops out along the northern edge of the subbasin. (DWR, 2006) Imported State Project Water via Lake Piru release to Santa Clara River.

Potable Water Sources

Groundwater from Mound Basin, Ventura River Basin, Oxnard Plain Pressure Basin via Ventura Water System. Surface water from Ventura River diversion via Ventura Water System. Surface water from Lake Casitas via Casitas MWD to Ventura Water System.

Subsurface Hydrologic Connection to Other Groundwater Basins

Upgradient: Yes, Santa Paula groundwater basin.

East/Southeast: Yes, Oxnard Plain Forebay and Oxnard Plain Pressure groundwater basins. Flow into and out of basin dependent on groundwater levels.

DWR CASGEM Groundwater Basin Prioritization Level - Medium

Impact Comments: Some primary and secondary inorganic contaminants above the MCL (DWR Bulletin 118).

Groundwater Quality Trend Notes: Trend is relatively flat, or no clear trend ⇨; Level trending up ⇧; Level Trending down ⇩

East Las Posas Basin

Groundwater Basin Surface Area:	19,771 acres
Irrigated Acreage:	≈7,784 acres (estimate determined from Ventura County Ag Commissioner's data)
Watershed:	Calleguas Creek
Aquifers:	Unconfined and confined aquifers
DWR Groundwater Basin Designation and Size:	Los Posas Valley Basin (4-8). Surface area 42,353 acres. Note: DWR groups three County basins into Los Posas Valley Basin (4-8) (DWR, 2014)
CASGEM Basin Priority:	High
DWR Groundwater Basin Population:	39,385 (2010)

Known Water Supply Wells (as of Feb. 2016)

Number of Wells: 248
Active: 155
Destroyed: 59
Abandoned: 21
Can't Locate: 13

Self Reported Groundwater Extraction to FCGMA (as of March 30, 2016)

Agricultural Extractions: 20,915 AF/Yr

Municipal Extractions: 2,050 AF/Yr

Total: 22,964 AF/yr

2015 Groundwater Levels in General for All Wells Gauged by County

"Key" well 03N20W26R03S - December level was down 15.5 feet from the January measurement.

In general for 10 wells measured in 2015 in the basin, water levels declined over the course of the year from the 1st quarter reading to the last quarter reading.

2015 Groundwater Quality in General for All Wells Sampled by County

(13 wells)

The water type in 6 wells is calcium bicarbonate type and 7 wells are calcium sulfate type.

Primary MCL Exceedances for Nitrate >45mg/l?	Yes, 3 wells
Secondary MCL Exceedances for Chloride >250mg/l?	No
Secondary MCL Exceedances for TDS >500mg/l?	Yes, 9 wells
Secondary MCL Exceedances for Sulfate >250mg/l?	Yes, 4 wells

5 Year Groundwater Level Trend 2011 - 2015

"Key" well 03N20W26R03S: ⇧

The 5 year trend based on 2011 through 2015 potentiometric surface maps varies.

The majority of the wells in the basin show a downward trend while a few of the wells show a rising trend.

5 Year Groundwater Quality Trend 2011-2015

SWN	Nitrate	Chloride	TDS	Sulfate
02N20W09Q05/07S	⇧	⇨	⇨	⇨

03N19W29K07/08S	⇧	⇨	⇨	⇨
03N19W29K06S	⇧	⇨	⇨	⇨

Two wells are located in the south, three wells are located in the east.

Sources of Groundwater Recharge

Basin Recharge: Infiltration of precipitation, minor stream flow across outcrops of the Fox Canyon and Grimes Canyon gravels, and percolation from flow in the Arroyo Las Posas. (DWR, 2006) Imported State Project Water via injection in the Calleguas Municipal Water District ASR well field.

Potable Water Sources

Groundwater from East Las Posas basin. Imported State Project Water from Calleguas MWD to various purveyors.

Subsurface Hydrologic Connection to Other Groundwater Basins

West:Possible connection to West Las Posas basin in NW part of basin.

South/Southeast: South Las Posas Basin.

Southwest: Restrictive subsurface structure between Pleasant Valley basin and East Las Posas basin may cause spillover from East Las Posas to Pleasant Valley when basin is full.

DWR CASGEM Groundwater Basin Prioritization Level - High

Impact Comments: TDS is generally high in this basin. Pubic Comment includes reports of subsidence, overdraft and saline intrusion (chloride from adjacient basin?)

Groundwater Quality Trend Notes: Trend is relatively flat, or no clear trend ⇨; Level trending up ⇧; Level Trending down ⇩

West Las Posas Basin

Groundwater Basin Name:	West Las Posas
Groundwater Basin Surface Area:	14,715 acres
Irrigated Acreage:	≈9,950 (estimate determined from Ventura County Ag Commissioner's data)
Watershed:	Calleguas Creek
Aquifers:	Unconfined and confined aquifers
DWR Groundwater Basin Designation and Size:	Los Posas Valley Basin (4-8). Surface area 42,353 acres. Note: DWR groups three County basins into Los Posas Valley Basin (4-8) (DWR, 2014)

Wells are located in the southeast portion of the basin.

Sources of Groundwater Recharge

Basin Recharge: percolation of surface flow from the Santa Clara River and, some subsurface flow from Santa Paula Subbasin makes its way over or across the Oak Ridge fault. Some amount of irrigation return also occurs (DWR, 2006) Imported State Project Water via Lake Piru release to Santa Clara River.

Potable Water Sources

Groundwater from Oxnard Plain Forebay basin. Surface water from Santa Clara River diversion via United Water Conservation District. Groundwater from Oxnard Plain Pressure basin via Oxnard Water System. Imported State Project Water from Calleguas MWD via Oxnard Water System.

Subsurface Hydrologic Connection to Other Groundwater Basins

Upgradient: Yes, Santa Paula groundwater basin to the northwest and Oxnard Plain groundwater basin to the east and south.

Downgradient: Yes, Mound groundwater basin to the southwest. Oxnard Plain Pressure groundwater basin to the south and southwest. Flow into and out of Mound

DWR CASGEM Groundwater Basin Prioritization Level - High

Impact Comments: Saline intrusion, nitrates, pesticides, and PCBs have impacted some water wells per DWR Bulletin 118

Groundwater Quality Trend Notes: Trend is relatively flat, or no clear trend →; Level trending up ↑; Level Trending down ↓

South Las Posas Basin

Groundwater Basin Surface Area:	10,189 acres
Irrigated Acreage:	≈2,233 (estimate determined from Ventura County Ag Commissioner's data)
Watershed:	Calleguas Creek
Aquifers:	Unconfined and confined aquifers
DWR Groundwater Basin Designation and Size:	Los Posas Valley Basin (4-8). Surface area 42,353 acres. Note: DWR groups three County basins into Los Posas Valley Basin (4-8) (DWR, 2014)
CASGEM Basin Priority:	High
DWR Groundwater Basin Population:	39,835 (2010)

Known Water Supply Wells (as of Feb. 2016)

Number of Wells: 171
Active: 28
Destroyed: 80
Abandoned: 21
Can't Locate: 42

Self Reported Groundwater Extraction to FCGMA (as of March 30, 2016)

Agricultural Extractions: 1,765 AF/Yr

Sources of Groundwater Recharge

Basin Recharge: Infiltration of precipitation, minor stream flow across outcrops of the Fox Canyon and Grimes Canyon gravels, and percolation from flow in the Arroyo Las Posas. (DWR, 2006)

Potable Water Sources

Groundwater from South and East Las Posas basins. Imported State Project Water from Calleguas MWD to various purveyors.

Subsurface Hydrologic Connection to Other Groundwater Basins

West/Northwest: East Las Posas groundwater basin.

DWR CASGEM Groundwater Basin Prioritization Level - High

Impact Comments: Some primary and secondary inorganic contaminants above the MCL (DWR Bulletin 118).

Groundwater Quality Trend Notes: Trend is relatively flat, or no clear trend →; Level trending up ↑; Level Trending down ↓

Cuyama Valley Basin

Groundwater Basin Surface Area:	16,560 acres
Irrigated Acreage:	≈1,410 (estimate determined from Ventura County Ag Commissioner's data)
Watershed:	Cuyama River
Aquifers:	Unconfined Aquifer
DWR Groundwater Basin Designation and Size:	Cuyama Valley (3-13) Surface area 242,114 Acres. (DWR, 2014)
CASGEM Basin Priority:	Medium
DWR Groundwater Basin Population:	1,236 (2010)

Known Water Supply Wells (as of Feb. 2016)

Number of Wells: 149
Active: 112
Destroyed: 7
Abandoned: 10
Can't Locate: 20

Water Demand Estimate

Irrigation Demand @ 2 AF/Ac*: 2,820 AF/Yr
Municipal/Domestic Demand @ 0.5 AF/person/Yr*: 618 AF/Yr
Total Estimated Demand*: 3,438 AF/Yr

*Actual demand is not known, typical demands are assumed for this estimate.

2015 Groundwater Levels in General for All Wells Gauged by County

Note: Wells are measured twice per year in the Cuyama Valley basin.

"Key" well 07N23W16R01S - Fall level was down 3.10 feet from the Spring measurement.

Both spring and fall measurements were obtained only on the above well in the basin in 2015.

2015 Groundwater Quality in General for All Wells Sampled by County

(3 wells)

The water type for all three samples is sodium bicarbonate type.

Primary MCL Exceedances for Nitrate >45mg/l?	No
Secondary MCL Excedances for Chloride >250mg/l?	No
Secondary MCL Excedances for TDS >500mg/l?	Yes, 3 wells
Secondary MCL Excedances for Sulfate >250mg/l?	No

Arroyo Santa Rosa Basin

Groundwater Basin Surface Area:	3,270 acres
Irrigated Acreage:	≈1,755 (estimate determined from Ventura County Ag Commissioner's data)
Watershed:	Calleguas Creek
Aquifers:	Unconfined and confined aquifers
DWR Groundwater Basin Designation and Size:	Arroyo Santa Rosa Valley Basin (4-7). Surface area 3,747 acres. (DWR, 2014)
CASGEM Basin Priority:	Medium
DWR Groundwater Basin Population:	2,211 (2010)

Known Water Supply Wells (as of Feb. 2016)

Number of Wells: 87
Active: 40
Destroyed: 33
Abandoned: 5
Can't Locate: 9

Self Reported Groundwater Extraction to FCGMA (as of March 30, 2016) (West part of basin only)

Agricultural Extractions - 1,254 Af/Yr
Municipal, Industrial and Domestic - 0 Af/Yr

Water Demand Estimate (Whole basin)

Irrigation Demand @ 2 AF/Ac*:3,510 AF/Yr
Municipal Demand @ 0.5AF/person/Yr: 1,105
Total Demand Estimate: 4,615 AF/Yr
*Actual demand is not known, typical demands are assumed for this estimate.

2015 Groundwater Levels in General for All Wells Gauged by County

"Key" well 02N20W26B03S - December level was down 3.02 feet from the January measurement.

In general for 5 wells measured in 2015 in the basin, water levels declined over the course of the year from the 1st quarter reading to the last quarter reading.

2015 Groundwater Quality in General for All Wells Sampled by County

(4 wells)

The water type In 1 of the wells is magnesium bicarbonate type and 8 wells are magnesium sulfate type.

Primary MCL Exceedances for Nitrate >45mg/l?	Yes, 7 wells
Secondary MCL Excedances for Chloride >250mg/l?	No
Secondary MCL Excedances for TDS >500mg/l?	Yes, 9 wells
Secondary MCL Excedances for Sulfate >250mg/l?	No

Impact Comments: TDS is known to be high in some parts of the basin (DWR Bulletin 118)

Groundwater Quality Trend Notes: Trend is relatively flat, or no clear trend →; Level trending up ↑; Level Trending down ↓

Section 1.0
Introduction

This report is a summary of work activities by County of Ventura Groundwater Section staff during calendar year 2015. Because groundwater conditions change over time, this report is prepared annually. Approximately fifty percent of the County staff's time in the Groundwater Section is dedicated to conducting field work. The field work includes:

- Inspection of permitted well sealing for new wells,
- Inspection of permitted destruction of old wells,
- Quarterly groundwater elevation measuring of approximately 180 wells, and
- Fall groundwater quality sampling of water supply wells.

Field work is critical to the protection of groundwater quality and quantity by ensuring well seals are properly constructed as required by the California Department of Water Resources (DWR) and Ventura County Well Ordinances. Improperly constructed well seals have the potential to act as a conduit for migration of contaminants and poor quality groundwater into better quality water, degrading water quality over time. The County strives to reduce or eliminate the risk that improperly constructed well seals can pose to our groundwater basins. Groundwater elevation and water quality data collected during field activities is used to determine water level and water quality trends, and to create a database available to residents, consultants, and other professionals.

The County staff also conducts administrative work which includes issuing permits for wells and soil borings, review of Discretionary Entitlement permit applications, and California Environmental Quality Act (CEQA) project reviews. County staff reviews Discretionary Entitlement permit applications and CEQA projects to assess a project's potential to impact groundwater quality and quantity, surface water quantity, and to verify a permanent water supply. Review findings are provided to the County Planning Division.

2015 is the fourth consecutive below average precipitation year. Groundwater elevations in most of the County basins showed a continuing decline during this extended drought. Water quality data was collected between August and December 2015. Data from 28 of the 221 wells exceeded the State of California's maximum contaminant level (mcl) for nitrate.

This 2015 report is the second annual report that presents Basin Summary Sheets for high and medium priority basins (per the State of California Basin priority designations), and some additional basins that County staff felt appropriate to include. Past County annual reports focused on providing data with some general findings about basin water quality and water level trends. The new basin summary sheets are a one page data sheet that provides facts and figures, and any water level and water quality trend data. The method of describing trends in these sheets is more complete than past methods used in the County Annual Report, and we feel is a better summary.

1.1 – Summary of Accomplishments

Over the last 12 months the Groundwater Section:

- Issued 117 various types of well permits, including 49 for new water supply wells, 4 water supply well destructions and 7 for water supply well repairs or modifications. 78 inspections of sealing and perforation work were performed by Groundwater Staff.

- Sampled 221 wells as part of the annual groundwater sampling program. Analytical results are included in Section 3 and Appendix D.

- Measured the water level, quarterly, in approximately 200 wells countywide. Of the fourteen groundwater basin “Key” wells measured during spring 2015 six were higher than the 2014 spring measurement and eight had declined from the spring 2014 measurement levels.

- Completed spring and fall potentiometric surface maps for: the Santa Clara River Valley, Upper Aquifer System, and Lower Aquifer System for 2015.

- Assisted the Fox Canyon Groundwater Management Agency (FCGMA) and other departments and Agencies with groundwater and mapping needs.

- Collaborated with other agencies to compile semi-annual groundwater level data and uploaded it to the California Statewide Groundwater Elevation Monitoring (CASGEM) website.

- Completed review and conditioning of numerous discretionary entitlement permits and CEQA documents.

- Completed and published the 2014 Groundwater Section Annual Report.

1.2 - General County Information

The County of Ventura was formed on January 1, 1873, when it separated from Santa Barbara County and is one of 58 counties in the State of California. Geographically, the county offers 42 miles of coastline and the Los Padres National Forest, which accounts for 46% of the county's land mass in the northern portion of the county. Fertile valleys in the southern half of the county make Ventura County a leading agricultural producer. Together, farming and the Los Padres National Forest occupy half of the county's 1.2 million acres.

A mild year-round climate, along with scenic geography makes the area attractive to the 850,000 culturally and ethnically diverse people who call Ventura County home. The unincorporated areas, along with the ten incorporated cities of Camarillo, Fillmore, Moorpark, Ojai, Oxnard, Port Hueneme, Santa Paula, Simi Valley, Thousand Oaks, and San Buenaventura (Ventura) ranks Ventura as the 11th most populous county in the State.

The following sections contain a general overview regarding population, climate, surface water and changes in groundwater conditions in Ventura County for 2015.

1.2.1 – Population

On May 1, 2015, the California State Department of Finance estimated Ventura County's population to be 848,073, an increase of 0.7 percent over the revised 2014 population estimate of 842,385. The Cities of Port Hueneme and Moorpark had the largest estimated percentage increase in population (1.7 and 1.6 percent respectively) over the previous year. Ventura County's population is expected to exceed 900,000 by the year 2025.

1.2.2 - Climate

The mean annual daily air temperature at the National Weather Service Oxnard area office was 68.1[1] degrees Fahrenheit, with an average daily high of 79.3[1] degrees Fahrenheit and an average low of 57.0[1] degrees Fahrenheit. The average annual rainfall, countywide (based on preliminary data from all active rain gages), was approximately 12 inches for the 2014/2015 water year[2]. Throughout the County, precipitation for the 2014/2015 water year was generally less than normal and ranged between 42 and 80 percent of normal. Oak View received 42% of normal, while the Camarillo area received 80% of the normal rainfall total. Figure 1-1 shows various rain gage/area rainfall totals comparing water year 2014/2015 to normal precipitation totals for that gage/area. Normals are determined from the 1957-1992 base period (i.e. the most recent 35 year period that represents average rainfall from gages with 80-120 years of record). Figure 1-2 shows a generalized distribution of rainfall across the county for wetter water years (2009 to 2010 and 2010 to 2011) and for drier water years (2013 to 2014 and 2014 to 2015). Figure 1-3 depicts average rainfall for the periods from 1995 to 1996 and 2014 to 2015 for all of Ventura County.

[1] Based on *preliminary* data from the National Climatic Data Center http://www.ncdc.noaa.gov.

[2] Water Year defined as: October 1 to September 30 of the following year. VCWPD precipitation data is *preliminary* and subject to change.

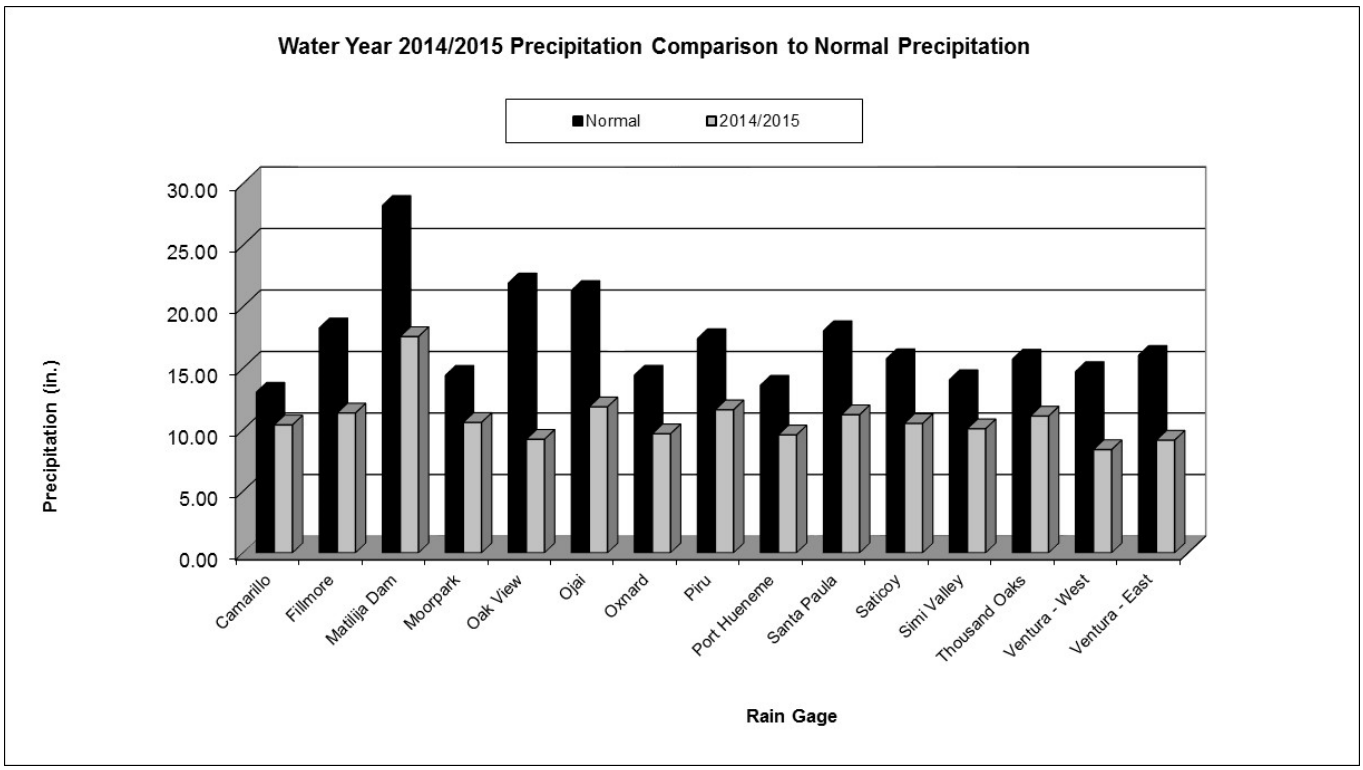

Figure 1-1: Chart comparing 2014/2015 rainfall totals to normal rainfall totals for the same area.

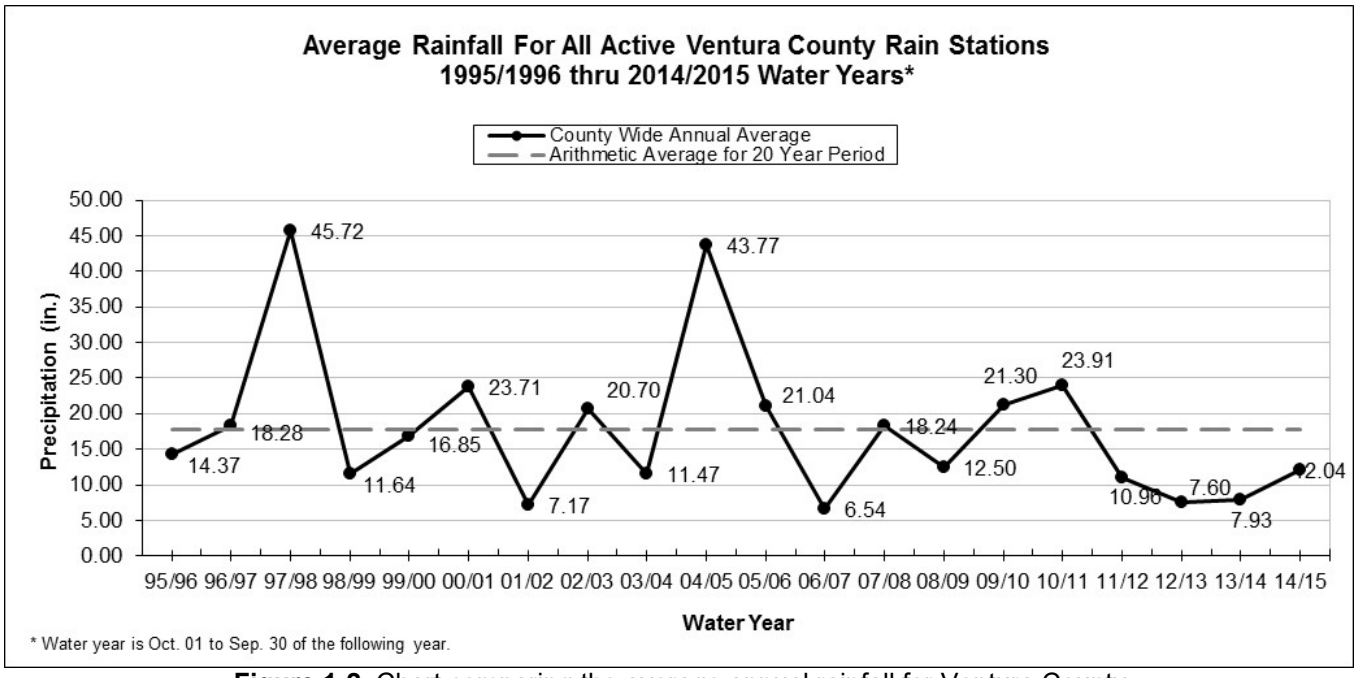

Figure 1-2: Chart comparing the average annual rainfall for Ventura County.

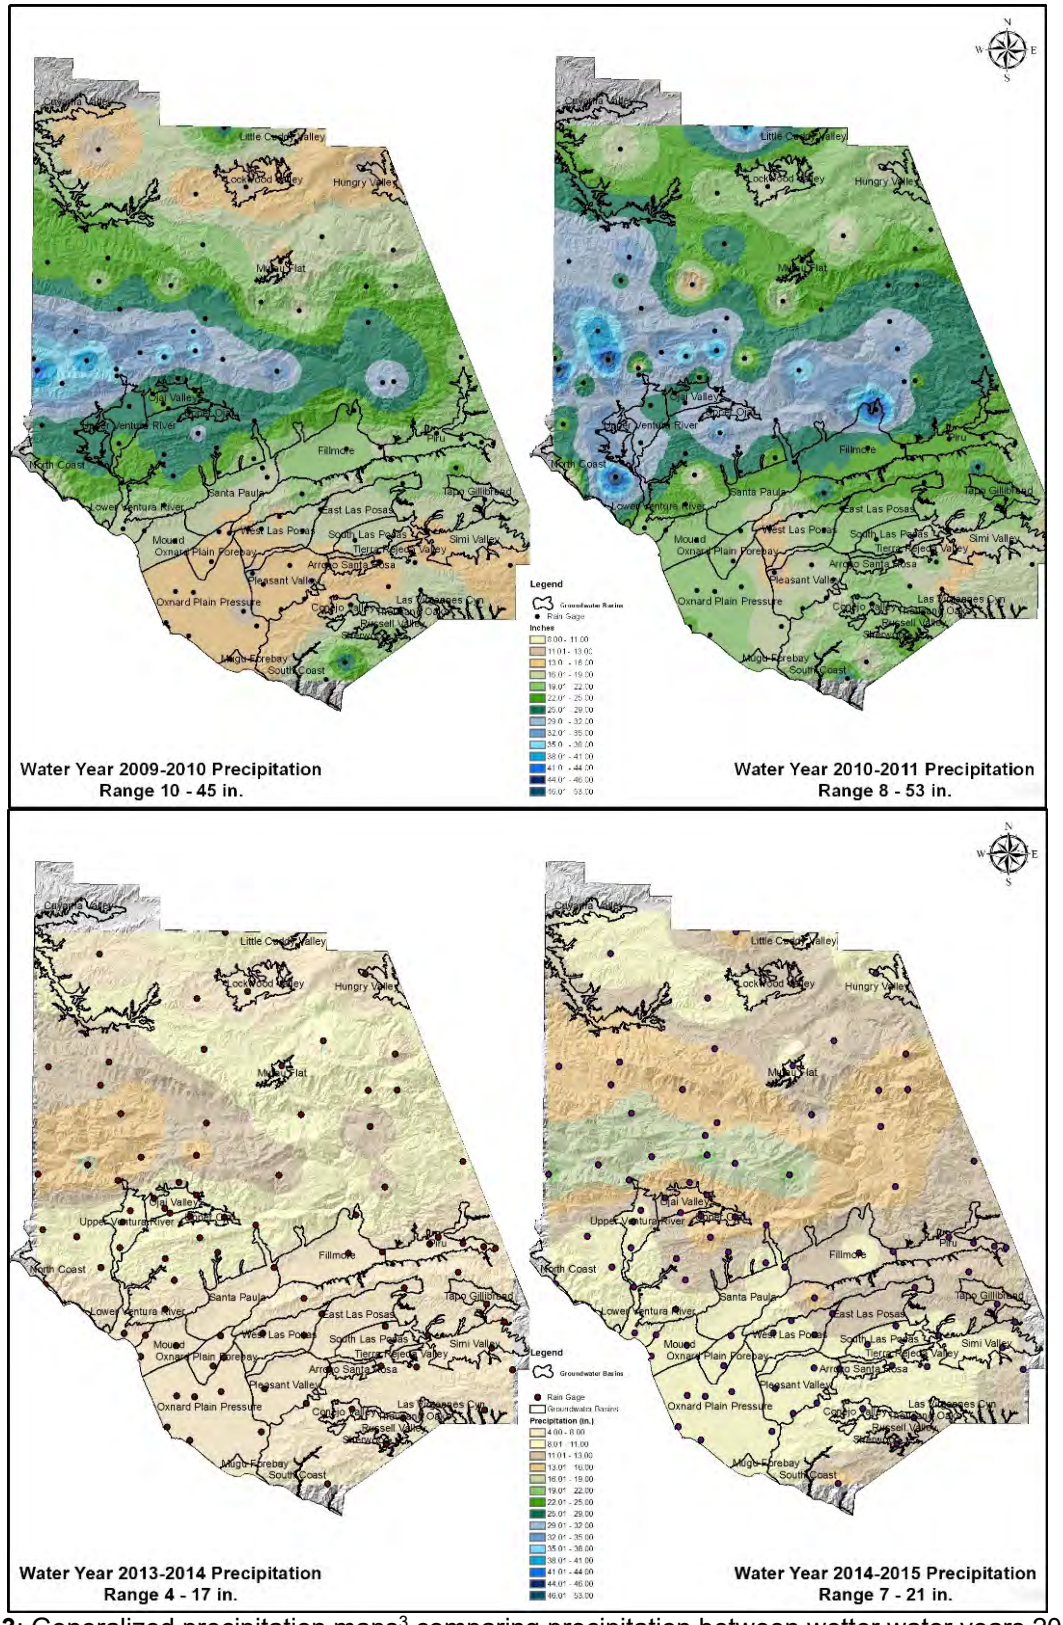

Figure 1-3: Generalized precipitation maps[3] comparing precipitation between wetter water years 2009/2010, 2010/2011 and drier water years 2013/2014 and 2014/2015.

[3] Based on data from all active Ventura County rain gages. Data is *preliminary* and subject to change.

1.2.3 – Surface Water

The presence of surface water is an important consideration in a groundwater conditions report because surface water resources may be hydrologically linked to groundwater resources. The natural connection between surface water and groundwater is typically understood in natural recharge of aquifers from surface water (losing streams), and discharge of groundwater to surface water (gaining streams). Surface water diversions to agriculture allow for use of surface water instead of extracting groundwater. Use of surface water to artificially recharge groundwater is an important part of conjunctively using surface and groundwater together.

In calendar year 2015 United Water Conservation District (UWCD) released approximately 6,533[4] acre feet (AF) of water from Lake Piru, which includes a fish passage requirement of 5 cubic feet per second (cfs) per day (3,622 AFY). UWCD diverted 2,640[4] AF from the Santa Clara River at the Freeman Diversion Dam with 1,231[4] AF sent to the Saticoy Spreading Grounds, 1,285[4] AF sent to the El Rio Spreading Grounds and 0[4] AF sent to the Noble pit, with some surface water also going to agricultural customers through the Pumping Trough Pipeline (PTP) and the Pleasant Valley Pipeline (PVP). At the end of 2015 there was 11,534[4] AF of water in storage in Lake Piru, 103,886[5] AF in Lake Casitas and 9,360[6] AF in Lake Bard. Casitas Water District releases 3,200 AF per year from Lake Casitas for the Robles Diversion Fish Passage.

In the Oxnard Plain, calendar year 2015 included reduced diversions of surface water for direct agricultural use and groundwater recharge. The reductions were a funciton of climatic conditions (drought) and regulatory constraints on releases of surface water from Lake Piru.

[4] Data provided courtesy of UWCD is preliminary and subject to change per UWCD. Freeman diversion data from UWCD operations logs.
[5] Data provided courtesy of Casitas MWD.
[6] Data provided courtesy of Calleguas MWD.

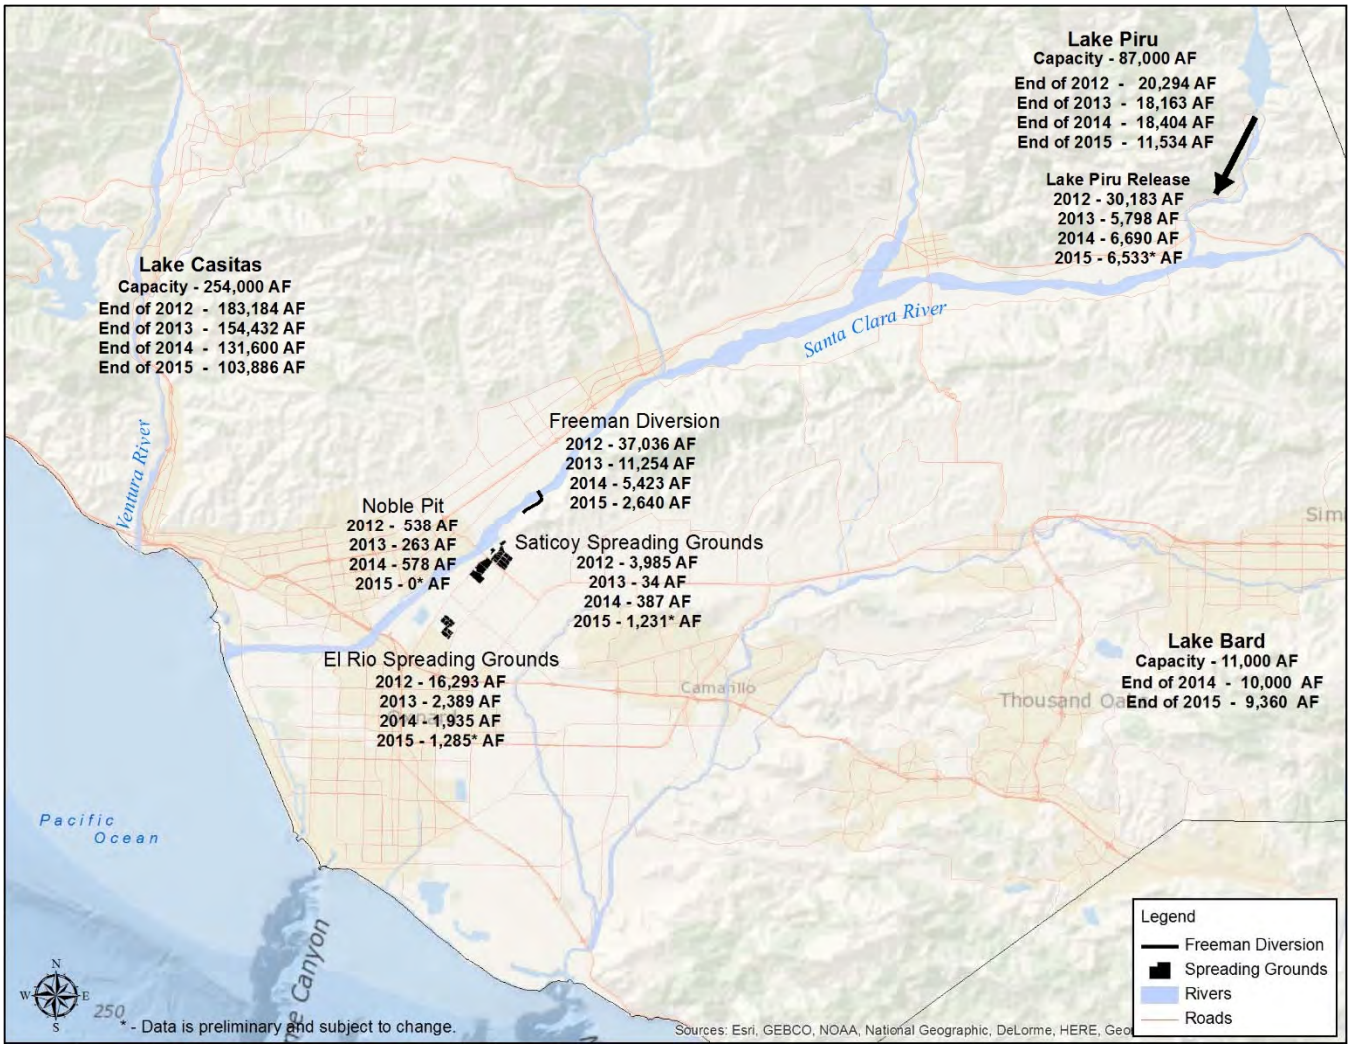

Figure 1-4: Map showing lake storage at the end of 2015 and Santa Clara River diversions.

1.2.4 – Groundwater

The majority of accessible groundwater is found in 32 groundwater basins within Ventura County. The group of basins in the south half of the County contain the largest groundwater reserves. The degree of interconnectedness of groundwater basins and aquifers within each basin is highly variable. Groundwater basins in the north half of the County do not join directly with other basins, while some groundwater basins in the south half of the County are connected on the surface and in the subsurface to varying degrees. The Groundwater Section of the Ventura County Watershed Protection District, the United Water Conservation District, dozens of individual water purveyors, and to a lesser extent the United States Geological Survey, all collect data to provide information concerning the status of groundwater in the County. Recharge of groundwater occurs naturally from infiltration of rainfall and river/streamflow, artificially through injection of imported water (Calleguas Municipal Water District) and spreading of diverted river water into recharge basins (United Water Conservation District).

Groundwater extraction data in certain basins is known and presented later in this report. Groundwater extraction data has been coarsely estimated in other basins.

Figure 1-5: Map showing groundwater basins in Ventura County.

Section 2.0
Duties and Responsibilities

2.1 – Well Ordinance

The County's Well Ordinance was updated in 2014 with the goal of regulating well construction, destruction, and operation in a manner designed to protect groundwater quality and quantity. The ordinance was updated to better align with the Sustainable Groundwater Management Act (SGMA). SGMA requires development of groundwater sustainability plans and sustainable management of our groundwater basins at the local level. The well ordinance update effort was significant, and opened up dialogue between the County and stakeholders regarding how well permits and well operation should be regulated. Overall the effort is considered a success and the County appreciates the input from its stakeholders in the process. The County's well ordinance follows well construction and destructions requirements set forth by the State of California Department of Water Resources.

2.1.1 – Permits

Permits are required in the County for construction and destruction of wells and soil borings such as groundwater extraction wells, cathodic protection wells, monitoring wells, and geotechnical borings. Permits are required to ensure wells and borings are properly constructed and sealed to mitigate the likelihood of migration of contaminants and poor quality water into better quality water and to document well construction details and well placement. After County staff issues a well permit, staff inspects placement of well seals to verify that the well was sealed per the California DWR Well Standards.

The Groundwater Section issues permits for wells and engineering test holes throughout the County, except within the City of Oxnard, which issues their own well permits within the City of Oxnard boundaries. The Groundwater Section conditioned and issued 117 permits for wells and engineering test holes during calendar year 2015. Table 2-1 below shows the total number of permits issued for the year by type of permit. Figure 2-1 below shows the total number of permits issued per year for the period 2006 to 2015.

Table 2-1: Permits issued by type for calendar year 2015.

Type of Work	Engineering Test Hole	Monitoring Well – Destruction	Monitoring Well – New	Water Supply Well – New	Water Supply Well – Destruction	Water Supply Well - Repair	Cathodic Protection Well	Geothermal Heat Exchange	**TOTAL**
Number 2015	22	11	23	49	4	7	1	0	117

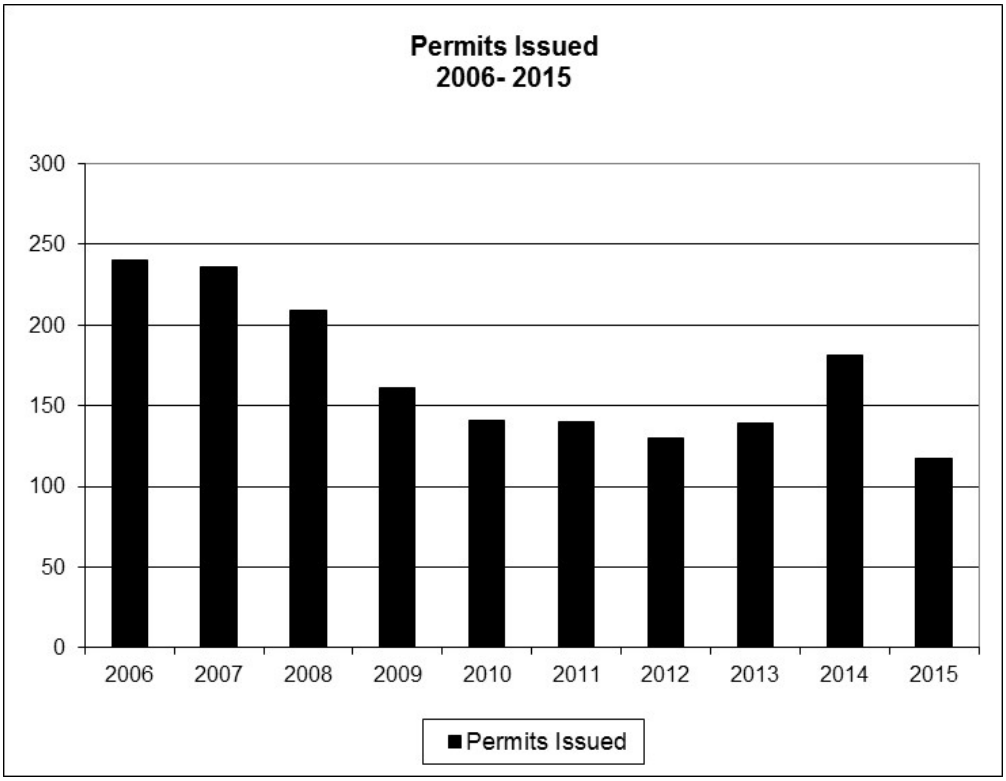

Figure 2-1: Permits issued for the period 2006 to 2015.

2.2 – Inspections

Groundwater Section staff perform inspections on all well perforation and sealing work for each new water supply well, water well destruction, new cathodic protection well or destruction, and major modifications or repairs to existing water supply wells per the County's Well Ordinance. In 2015, staff performed 78 inspections throughout the County. Figure 2-2 shows the distribution of new well and well destruction locations inspected by Groundwater staff during 2015.

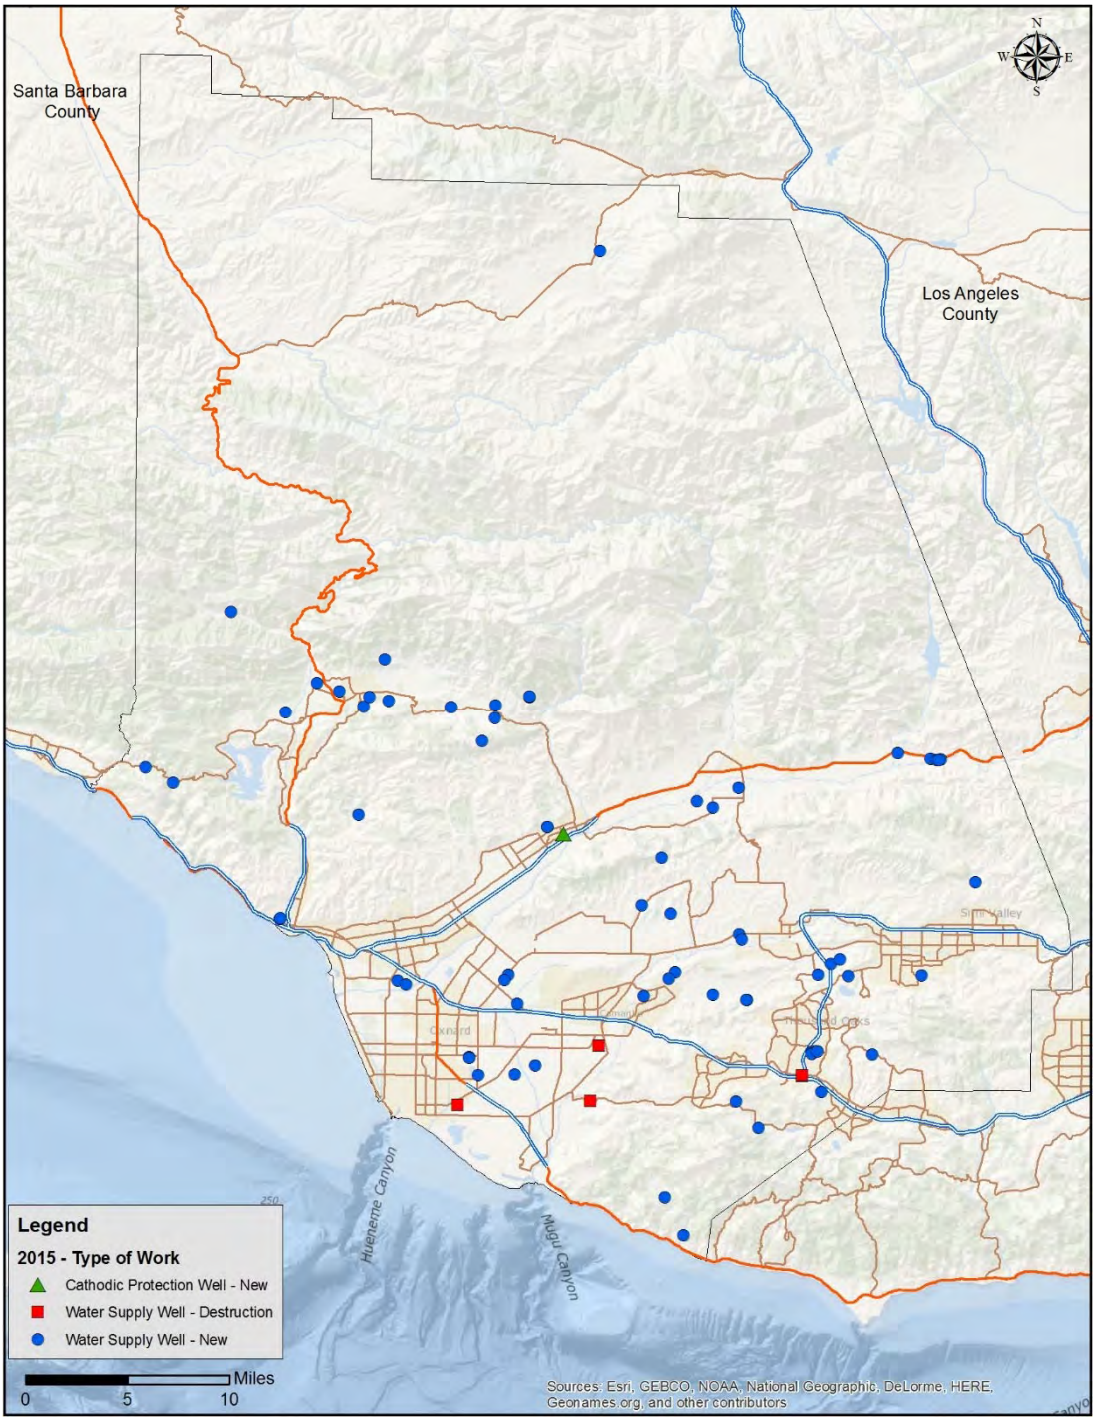

Figure 2-2: Location of well inspections in 2015.

2.3 – Inventory and Status of Wells

The Groundwater Section maintains an inventory of wells and their status in a database. There are several purposes of maintaining this information which include verifying well locations, tracking owner-reported well operation in order to determine if a well is abandoned, tracking well ownership, and assisting land owners in determining if wells are on particular parcels. The database contains details for wells of all types including water supply wells, long-term monitoring wells, cathodic protection wells, and also springs that were given a state well number. At the end of 2015 there were 9,054 well records in the database in the following categories.

2015 Status	Number
Active	4,016
Abandoned	416
Can't Locate	1,821
Non Compliant	88
Non Compliant Abandoned	136
Destroyed	2,562
Exempt	15

- Active wells are those wells that meet or exceed the minimum requirement of 8 hours pumping per calendar year as described in the County of Ventura Well Ordinance No. 4468.
- Abandoned wells are those wells that do not meet the 8 hour minimum usage requirement or are in a condition that no longer allows the well to be used.
- 'Can't Locate' wells are old rural wells for which the Groundwater Section has historic well location data but the locations are now in areas that have subsequently been urbanized. There are several reasons why a well may be listed as "Can't Locate." The current owner of the property where the historical well was understood to be located may be unaware of the existence of a well on his/her property, or an approved search has been conducted and no well has been found.
- Non-Compliant wells are generally active wells where the owner of the well has failed to respond to written communication from the Groundwater Section.
- Non-Compliant Abandoned wells are those wells where the owner of an abandoned well has failed to respond to written communication from the Groundwater Section to take action on an inactive well. The County's Well Ordinance prohibits anyone from owning an abandoned well. Abandoned wells pose a safety risk and may also act as a potential pathway for contaminants to reach groundwater.
- Destroyed wells are wells that have been properly destroyed under permit.
- Exempt wells are wells that have been found to be in good enough condition to remain inactive for a period of 5 years before being re-activated or re-inspected. To be listed as exempt, a well inspection report from a professional geologist or civil engineer and application fee, must be submitted by the well owner to the Groundwater Section for review and approval.

Section 3.0
Groundwater Quality

3.1 – Water Quality Sampling

The Groundwater Section collects water quality data to analyze and obtain a general overview of the quality of the groundwater in Ventura County groundwater basins. We also work with and share groundwater quality data with other data collecting organizations in the County. This is very important as there is no other systematic county wide groundwater quality monitoring program in place. Without the data, groundwater quality may not be known. Collected data is publically available, upon request, and is also used by stakeholders, consultants, and other professionals.

In 2015, Groundwater staff sampled a total of 221 water supply wells throughout the County. The well sampling procedures include contacting well owners to get approval to sample wells, obtaining sample bottles from the laboratory, collecting water samples, delivering the samples to the laboratory within the sample holding times, receiving the water quality analyses from the lab, entering water quality data in the database, and providing a copy of the data to the well owner. Because the County does not own or operate the wells it samples (with some very limited exceptions) it relies on well owner permission to make their wells available. Some of the wells sampled are large capacity wells and are only sampled when normally in operation. The County works to sample many of the same wells each year, but because the County does not own most of the wells, it is not always able to control the well's availability for sampling. Sometimes wells are not available to sample for various reasons, e.g. the pump is being repaired, rainy weather makes pumping unnecessary, lock on gate changes, etc. When a preferred well cannot be sampled, County staff will seek to find an alternative well to sample. The process is flexible, but can also be limiting because County staff may not always be able to sample the same well year after year, and long term water quality from individual wells is valuable to determine water quality trends.

All samples were analyzed for irrigation suitability to determine the concentration of general minerals (see Appendix D – Water Quality Section). Analyses were conducted by Fruit Growers Laboratory in Santa Paula. California Title 22 metals were also analyzed on select samples and eleven samples were analyzed for Gross Alpha particles. Analytical results were entered into the Section's database and used to describe the chemistry of groundwater in the basins sampled. Complete results are listed in Appendix D, and general interpretations of the data are detailed in the following sub-sections. Because the wells sampled each year may vary care must be taken when comparing data from past reports. We make an effort to sample certain wells every year and sample additional wells as time and budget allow. Wells sampled in the north half of the County are shown in Figure 3-1. Wells sampled in the south half of the County are shown in Figure 3-2.

Additional groundwater quality data that was not used in this report is available from other sources, including data from water districts and agencies that collect and analyze groundwater samples for their own use. Organic groundwater chemistry data is also available for some areas of the County through the State Regional Water Quality Control Board's Geotracker website for environmental cleanup sites.

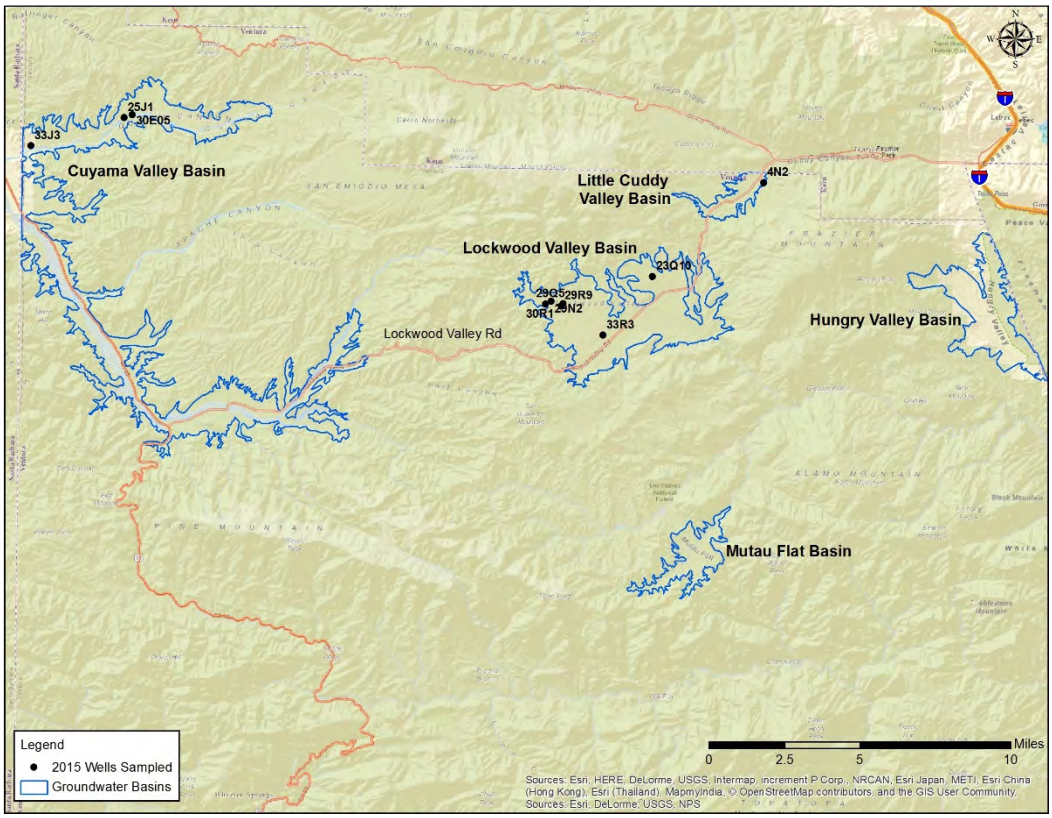

Figure 3-1: Map depicting sample locations for the northern half of the County.

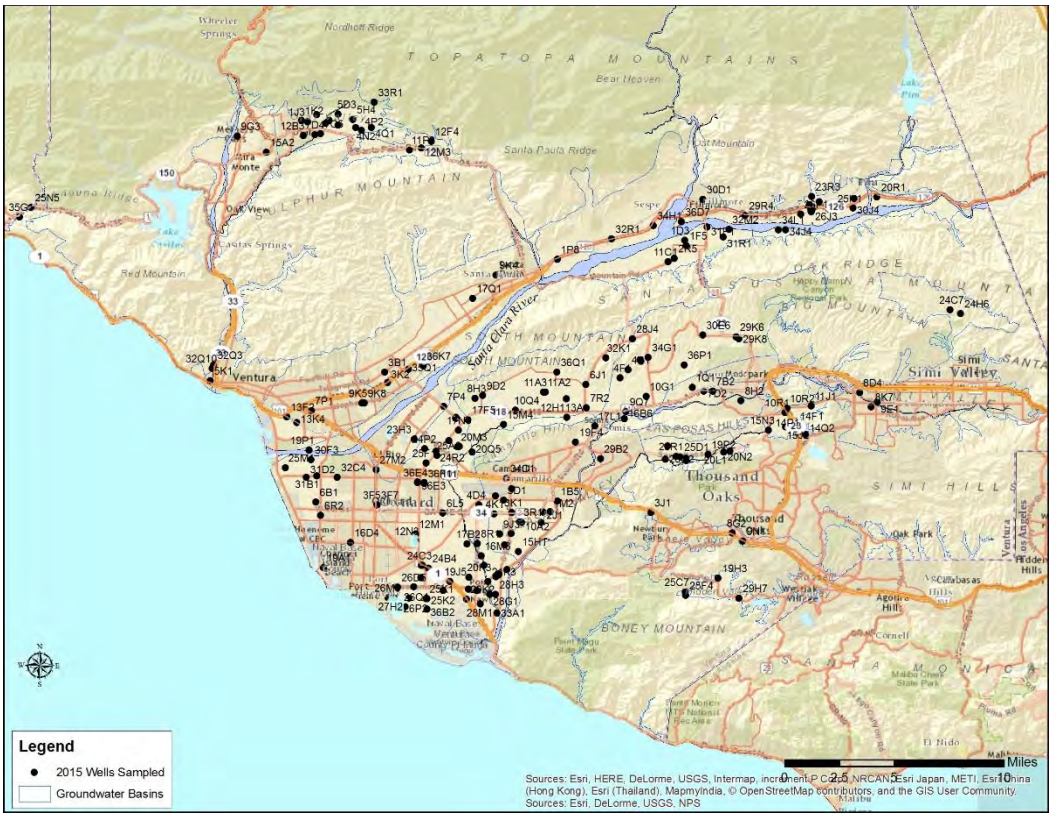

Figure 3-2: Map depicting sample locations for the south half of the County.

3.2 – Current Conditions

General interpretations of the groundwater quality data for each groundwater basin sampled this year is included in this section. Unless otherwise listed, the data interpretation is limited to data collected by the County staff. Basin summaries are presented in order from largest to smallest total available storage capacity as reported in California Department of Water Resources Bulletin No. 118. Ventura County groundwater, in general, has slightly high total dissolved solids and sulfate (SO_4^{2-}). Several areas are nitrate impacted (meaning Basin Management Water Quality Objectives for nitrate are exceeded).

The Groundwater Section uses the United States Environmental Protection Agency (EPA) National Drinking Water Regulations and California Code of Regulations (CCR) Title 22, Section 64431 (Table 3-1 below) for describing groundwater quality in Ventura County relative to maximum contaminant levels (MCL). National Primary Drinking Water Regulations, or primary standards, are legally enforceable standards that apply to public water systems. Primary standards protect public health by limiting the levels of contaminants in drinking water. Maximum contaminant level or MCL is the highest level of a contaminant allowed in drinking water by the United States Environmental Protection Agency. MCLs are set as close as feasible to the level that below which there is no known or expected health risk. National Secondary Drinking Water Regulations, or secondary standards, are guidelines for contaminants that may cause cosmetic effects (such as skin or tooth discoloration) or aesthetic effects (such as taste, odor, or color) in drinking water. The EPA recommends secondary standards to water systems but does not require systems to comply with the secondary standards. However, states may choose to adopt the secondary standards as enforceable standards. CCR, Title 22, Section 64431 lists MCLs for metals adopted by the State of California. In order to be certified as a permanent domestic or municipal water supply, water from wells located in the County of Ventura must meet these standards.

Table 3-1: U.S. Environmental Protection Agency Primary and Secondary Standards and California Code of Regulations, Title 22 Maximum Contaminant Levels (February 2012).

Primary Contaminants	Chemical Formula	EPA MCL (mg/l)	CCR, Title 22 MCL (mg/l)
Antimony	Sb	0.006	0.006
Arsenic	As	0	0.01
Asbestos		7 MFL[1]	7 MFL[1]
Barium	Ba	2	1
Beryllium	Be	0.004	0.004
Cadmium	Cd	0.005	0.005
Chromium	Cr	0.1	0.05
Copper	Cu	1.3	
Cyanide		0.2	0.15
Fluoride	F^-	4	2
Lead	Pb	0	
Mercury	Hg	0.002	0.002
Nitrate (as Nitrogen)	N	10	10
Nitrate[2]	NO_3^-		45
Nitrite (as Nitrogen)	N	1	1
Selenium	Se	0.05	0.05
Thallium	Tl	0.0005	0.002

Table continued from previous page **Secondary Contaminants**			
Aluminum[3]	Al	0.5 to 0.2	
Chloride	Cl^-	250	
Iron	Fe	0.3	
Manganese	Mn	0.05	
pH		6.5-8.5	
Silver	Ag	0.1	
Sulfate	SO_4^{2-}	250	
Total Dissolved Solids	TDS	500	
Zinc	Zn	5	

[1] MFL = Million fibers per liter longer than 10 um

[2] CCR, Title 22 standard for Nitrate reported as NO_3

[3] CCR, Title 22 lists Aluminum as a primary contaminant

The major ionic species in most natural waters are Na^+, K^+, Ca^{++}, Mg^{++}, Cl^-, CO_3^{2-}, HCO_3^-, and SO_4^{2-}. As water flows through an aquifer it assumes a diagnostic chemical composition from interactions with the lithology. One of the more widely used ways to present water chemistry graphically is the trilinear or piper diagram. The diagram is comprised of three pieces: a ternary diagram in the lower left representing the cations (positive charged ions), a ternary diagram in the lower right representing the anions (negative charged ions), and a diamond plot in the middle representing a combination of the two. The diamond diagram tells you different things depending on what you're plotting. For groundwater, the top quadrant is calcium sulfate waters, the left quadrant is calcium bicarbonate waters, the right quadrant is sodium chloride waters, and the bottom quadrant is sodium bicarbonate waters. Figure 3-3 shows the form of a piper diagram.

The first step in determining the water type is to convert the concentration of each anion or cation group in a sample to milliequivalents/L (meq/L) and normalize the concentrations. The percent concentrations are then plotted on the appropriate ternary diagram. The position of the points are projected parallel to the magnesium and sulfate axes, respectively until they intersect in the center field (Fetter, 1988). Piper diagrams for each basin are located in Appendix D starting on pg. 140.

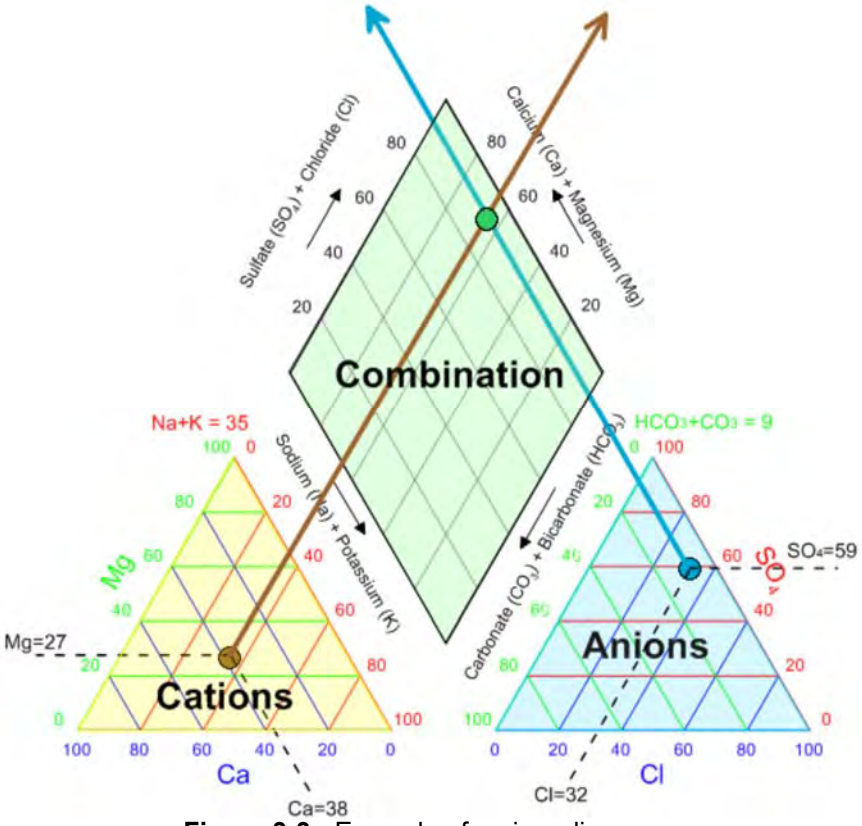

Figure 3-3: Example of a piper diagram.

Figure 3-4 shows a plot of the water quality from a well sampled this year. The cations plot as calcium type on the cations triangle and the anions plot in the sulfate type on the anions triangle. Positions of the points projected on to the diamond shaped center field shows the water is calcium sulfate type.

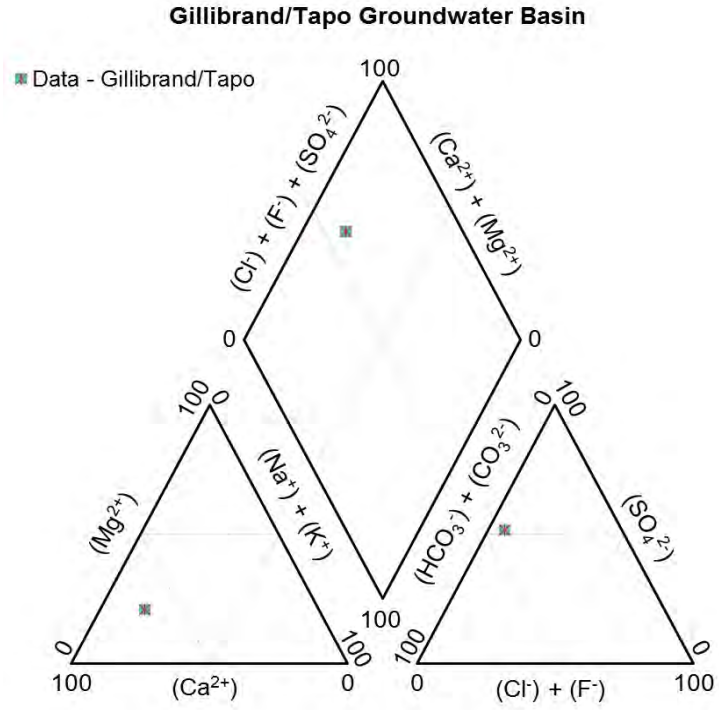

Figure 3-4: Piper diagram showing water quality of a well from Gillibrand/Tapo groundwater basin.

A second method to present results, a stiff diagram, is shown in Figure 3-5. The same cations and anions that are plotted in the piper diagrams are also shown in the stiff diagrams. The ions are plotted on either side of a vertical axis in milliequivalents per liter (meq/L), cations on the left of the axis and anions on the right. The polygonal shape created is useful in making a quick visual comparison between water from different sources. Stiff diagrams for wells sampled this year are included on each basin map.

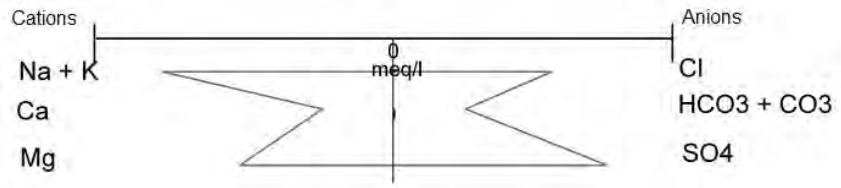

Figure 3-5: Example stiff diagram.

3.2.1 - Oxnard Plain Pressure Basin

The Oxnard Plain Pressure Basin is the largest and most complex of the groundwater basins in Ventura County. The Oxnard Plain Pressure Basin consists of two major aquifer systems. The Upper Aquifer System (UAS) consists of, from shallowest to deepest, the Perched, Semi Perched, Oxnard, and Mugu aquifers. Of the UAS aquifers, only the Oxnard and Mugu aquifers are sampled for water quality by the County. The Lower Aquifer System (LAS) consists of, from shallowest to deepest, the Hueneme, Fox Canyon and Grimes Canyon aquifers. There are approximately 895 water supply wells in the Oxnard Plain Pressure Basin; 371 are active. There are no wells perforated solely in the Grimes Canyon aquifer so the County cannot sample it specifically. The basin map in Figures 3-6 thru 3-8 show approximate well locations and (in call out boxes) concentrations of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the Upper Aquifer System of the Oxnard Plain Pressure Basin. Figures 3-9 and 3-10 show the same information for wells sampled in the Lower Aquifer System.

3.2.1.1 - Oxnard Aquifer (UAS)

The Oxnard aquifer is the shallowest of the confined aquifers. The Oxnard aquifer is the most developed (based on the number of wells) production zone. Average depth to the main water bearing material is 80 feet making it the easiest and least expensive aquifer in which to construct a water supply well. The piper diagram, Figure E-1 shows low variability in water quality of the wells sampled this year. There is no dominant cation, though data plot closest to a calcium cation type; sulfate is clearly the major anion. The water is best classified as a calcium sulfate type. Groundwater samples were collected from nine wells in the Oxnard Aquifer. A comparison of the stiff diagrams with those from the 2014 report shows no significant change in water quality type.

Water from one of the wells has a concentration of iron (Fe) and water from four of the wells have manganese (Mn) concentrations above the secondary MCL for drinking water. Samples from all twelve of the wells have sulfate (SO_4^{2-}) and TDS concentrations above the secondary MCL for drinking water; sulfate concentrations range from 350 to 2050 mg/L. Total dissolved solids (TDS) ranged from 829 to 4043 mg/l. Water from two of the wells sampled have nitrate (NO_3^-) concentration above the primary MCL for drinking water. Samples from four wells were analyzed for Title 22 metals. Lead concentration was above the MCL for drinking water. The concentrations of all other Title 22 metals were below the MCL for drinking water.

Groundwater plumes with elevated nitrate concentrations are common in the northern portion of the basin. Sources of nitrate are nitrogen based fertilizers in agricultural areas and septic systems in residential areas.

3.2.1.2 - Mugu Aquifer (UAS)

The Mugu aquifer is the lowest layer of the UAS and has similar physical and chemical characteristics to the Oxnard Aquifer, but has slightly better water quality, in part, because with increasing depth contaminants are generally less likely to infiltrate. This is shown graphically in the piper diagram, Figure E-2, and stiff diagram Figure 3-7. Average depth to the main water bearing material is 200 ft. Five wells that are perforated only in the Mugu aquifer were sampled. The piper diagram, Figure E-2, shows low variability in water quality of the wells sampled this year. There is no clearly dominant cation, though data plots closest to a calcium cation type; sulfate (SO_4^{2-}) is clearly the major anion. The water is best classified as a calcium sulfate type. All five wells sampled have TDS concentrations above the MCL for drinking water. TDS ranges from 898 to 1560 mg/l. All five wells sampled have sulfate (SO_4^{2-}) concentrations above the secondary MCL for drinking water, three wells have iron concentrations above the secondary MCL, three wells have manganese concentrations above the secondary MCL. One water sample was analyzed for Title 22 metals. The concentrations of all the Title 22 metals were below the MCL for drinking water.

Figure E-3, piper diagram shows water chemistry of Upper Aquifer wells that are screened in both the Oxnard and Mugu aquifers. It shows moderate variability in water quality of the wells sampled this year. There is no dominant cation but the data plots close to the calcium cation type; sulfate (SO_4^{2-}) is the dominant anion in seven of the samples, chloride is the dominant anion in one sample, and there is no dominant anion for two samples but the data plots close to the sulfate anion type. The water is calcium sulfate type. The piper diagram, Figure E-4, shows a comparison of all the wells sampled in the UAS. TDS ranges from 772 to 1920 mg/l. Five of the wells have iron concentrations above the secondary MCL, nine wells have manganese and sulfate (SO_4^{2-}) above the secondary MCL and all ten wells have TDS concentrations above the secondary MCL.

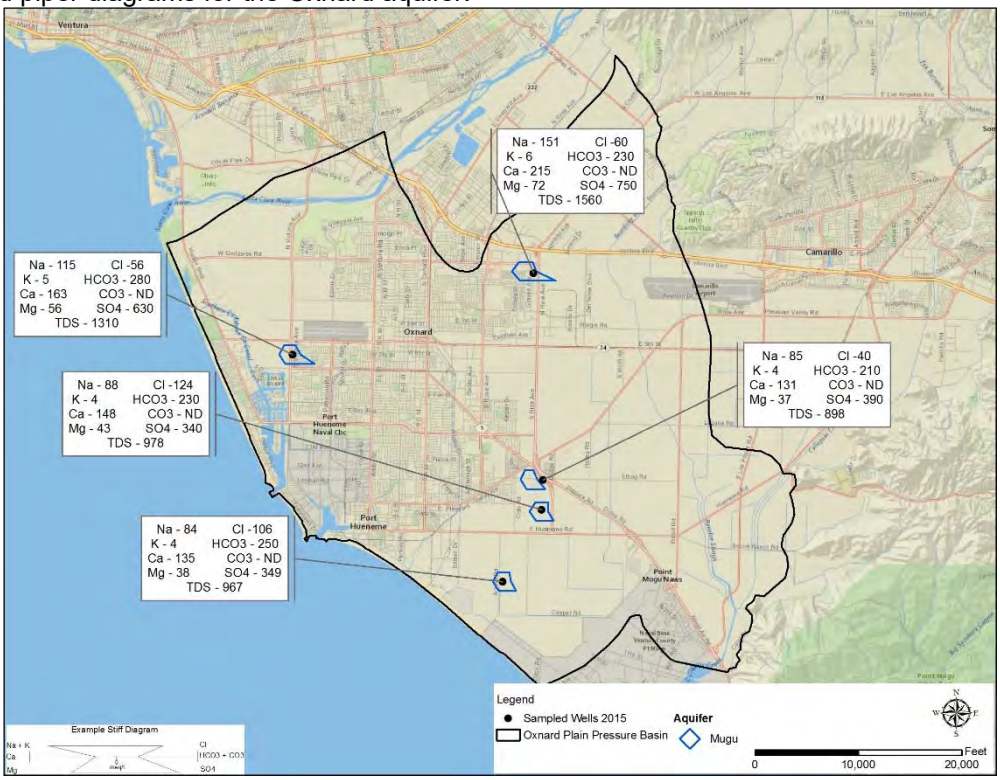

Figure 3-7: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams for the Mugu aquifer.

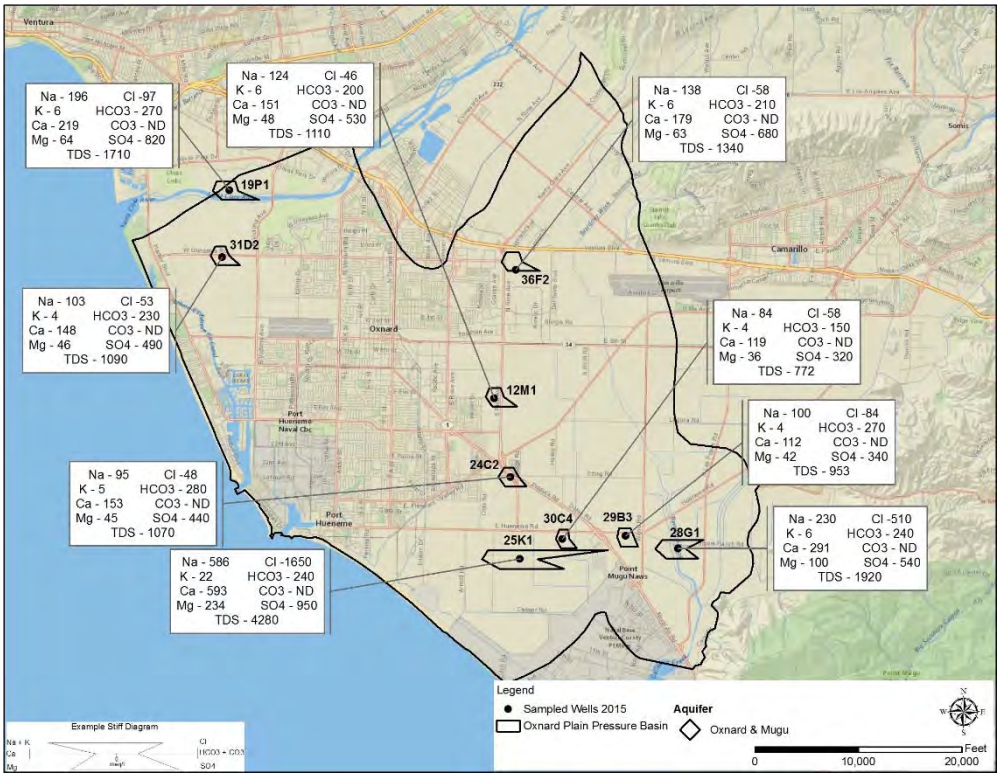

Figure 3-8: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams for wells screened in both the Oxnard and Mugu aquifers.

3.2.1.3 - Hueneme Aquifer (LAS)

The Hueneme aquifer is the shallowest of the Lower Aquifer System aquifers with depth to the main water bearing material approximately 375 feet. Very few wells are perforated exclusively in the Hueneme aquifer, making an accurate determination of water quality for the aquifer difficult. Five wells screened solely in the Hueneme aquifer were sampled this year. Figure E-5, piper diagram, shows low variability in water quality of the wells sampled this year. There is no clearly dominant cation, though the data plots closest to a calcium cation type; sulfate (SO_4^{2-}) is the major anion. The water is best classified as a calcium sulfate type. All five wells sampled have elevated TDS and sulfate (SO_4^{2-}) concentrations compared to the secondary MCL for drinking water. Two samples have iron and three samples have manganese concentrations above the MCL for drinking water. Overall, water quality has not changed significantly since the previous round of sampling.

3.2.1.4 - Fox Canyon Aquifer (LAS)

The Fox Canyon aquifer is the second most developed production zone in the Oxnard Plain Pressure Basin based on the number of wells and depth of perforations. Depth to the main water bearing material is approximately 580 feet. The Fox Canyon aquifer generally has excellent water quality and high yield rates, but is subject to seawater intrusion near Point Mugu and the Hueneme Submarine Canyon. Extractions are monitored and allocated by the Fox Canyon Groundwater Management Agency in order to mitigate aquifer overdraft and reduce the intrusion of seawater.

The piper diagram, Figure E-6, shows moderate to high variability in water quality of the wells sampled this year. Sodium is the dominant cation in two samples. There is no dominant cation in the remainder of the

samples. Bicarbonate is the dominant anion in two samples; two samples have no dominant anion; and sulfate (SO_4^{2-}) is the dominant anion in remaining 12 samples of the samples. The water type of the majority of the samples is calcium sulfate. There is more variation in water chemistry compared to last year. More wells were sampled and there is a higher concentration of calcium and sulfate. For wells perforated solely in the Fox Canyon Aquifer sampled this year, TDS concentrations range from 449 mg/l to 1050 mg/l; all 16 wells sampled have TDS above the secondary MCL for drinking water. Eight water samples have iron (Fe^{+}) concentrations above the secondary MCL for drinking water. One well had a concentration of iron (Fe^{+}) at approximately 45 times MCL. The same well had a manganese (Mn^{+}) concentration of almost 10 times the MCL. These high levels can be attributed to corrosion in the well or well equipment. The water came out black and would not clean up. Six water samples have manganese (Mn^{+}) and twelve have sulfate (SO_4^{2-}) concentrations above the secondary MCL for drinking water. Four samples were analyzed for Title 22 metals. One sample had lead above the MCL for drinking water. The concentrations of all remaining Title 22 metals were below the MCL for drinking water.

Six of the Oxnard Plain Pressure Basin wells that were sampled this year are perforated in both the Hueneme aquifer and the Fox Canyon aquifer and will be referred to as LAS wells. Results for those wells are included in Appendix D and shown on the map of the Lower Aquifer System (LAS) Figure 3-10. The piper diagram, Figure E-7, shows moderate variability in water quality of the wells sampled this year. Sodium is the dominant cation in one sample with no dominant cation in the remainder, but samples plot close to the calcium cation type. Sulfate (SO_4^{2-}) is the dominant anion in five of the samples; there is no dominant anion in the remaining sample but it plots near the bicarbonate anion type. One water sample is sodium sulfate type and the remainder are calcium sulfate. TDS concentration of water from these wells varies between 859 mg/l and 1380 mg/l. Samples from four wells have iron above the secondary MCL and three have manganese concentrations above the secondary MCL for drinking water. Five have sulfate above the secondary MCL and all six have TDS concentrations above the secondary MCL for drinking water. Water samples from four of the Hueneme/Fox wells were analyzed for Title 22 metals. One sample has lead above the MCL but all remaining Title 22 metals were well below the primary MCL for drinking water.

Four of the Oxnard Plain Pressure Basin wells that were sampled this year are perforated in the Fox Canyon and the Grimes Canyon aquifers. They are also referred to as LAS wells. Results for those wells are included in Appendix D and shown on the map of the Lower Aquifer System (LAS) Figure 3-10. The piper diagram, Figure E-8, shows moderate variability in water quality of the wells sampled this year. Sodium is the dominant cation in three samples with no dominant cation in the fourth. Sulfate (SO_4^{2-}) is the dominant anion in one of the samples; there is no dominant anion in the remaining samples. Three water samples are sodium sulfate type and the remainder is calcium sulfate. TDS concentration of water from these wells varies between 886 mg/l and 1120 mg/l. Samples from three wells have iron above the secondary MCL and one has manganese concentration above the secondary MCL for drinking water. One has sulfate above the secondary MCL, one has chloride above and all four have TDS concentrations above the secondary MCL for drinking water. A water sample from one of the Fox/Grimes wells was analyzed for Title 22 metals. One sample has lead above the MCL but all remaining Title 22 metals were well below the primary MCL for drinking water.

Four of the Oxnard Plain Pressure Basin wells that were sampled this year are perforated in the Hueneme Fox Canyon and the Grimes Canyon aquifers. They are also referred to as LAS wells. Results for those wells are included in Appendix D and shown on the map of the Lower Aquifer System (LAS) Figure 3-10. The piper diagram, Figure E-9, shows moderate variability in water quality of the wells sampled this year. Sodium is the dominant cation in one sample with no dominant cation in the remaining three samples. Sulfate (SO_4^{2-}) is the dominant anion in one of the samples; there is no dominant anion in the remaining samples. Three water samples are calcium sulfate type and the remaining sample is sodium sulfate type. TDS concentration of water from these wells varies between 772 mg/l and 1370 mg/l. A sample from one well has manganese concentration above the secondary MCL for drinking water and one has sulfate above

the secondary MCL, and all four have TDS concentrations above the secondary MCL for drinking water. A water sample from one of the Fox/Hueneme/Grimes wells was analyzed for Title 22 metals. All Title 22 metals were well below the primary MCL for drinking water.

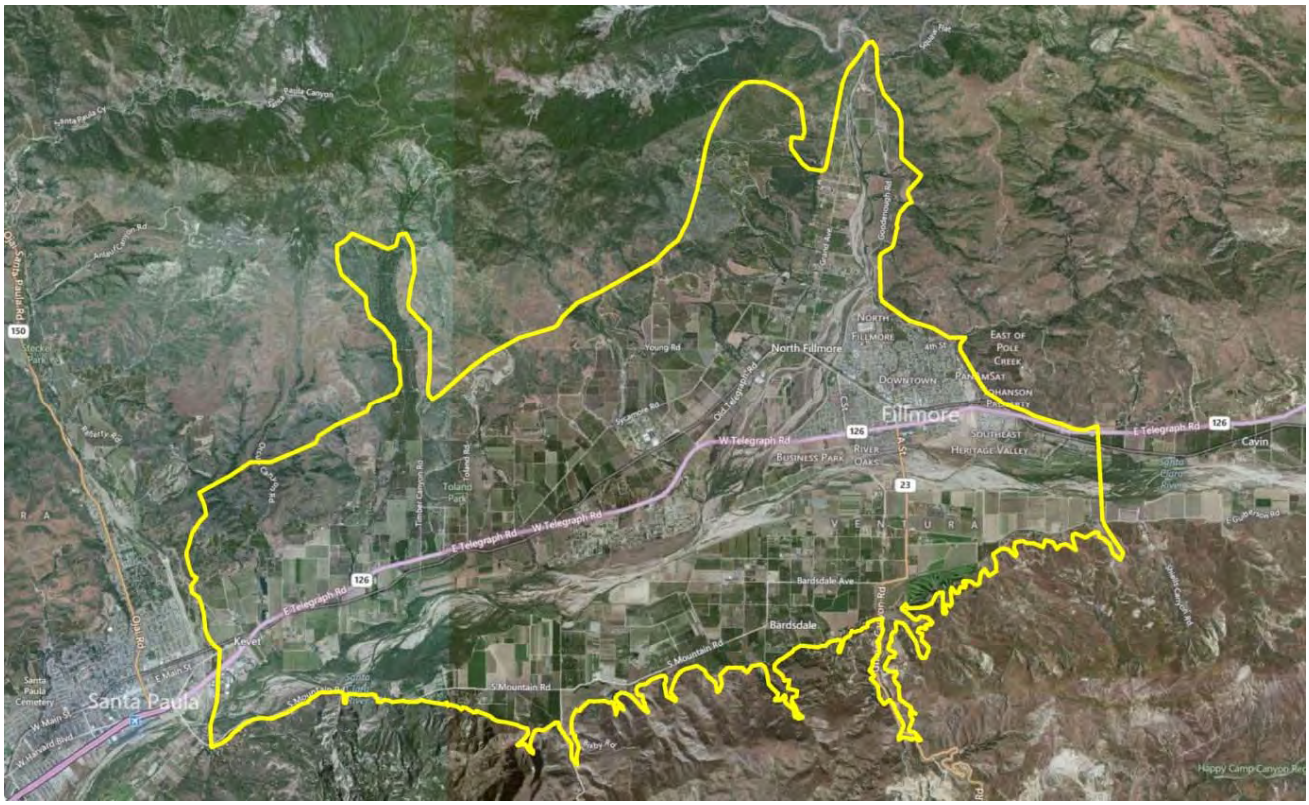
3.2.2 - Fillmore Basin

The Fillmore Basin, though small in geographic area, has a total aquifer thickness of almost 8,000 feet in some places. Despite the depth of the basin, County records indicate that water wells are generally no deeper than approximately 950 feet. Water quality can vary greatly depending on depth of the well. Shallow groundwater is generally younger and recharged by river flows. Deeper groundwater is older and has acquired chemistry through dissolution of constituents from the surrounding sediments. There are approximately 625 water supply wells in the Fillmore Basin; 454 are active. Historically, nitrate (NO_3^-) concentrations have been elevated, but of the thirteen wells sampled this year only two showed elevated NO_3^- concentration relative to the primary MCL for drinking water. The piper diagram, Figure E-12, shows low variability in water quality of the wells sampled this year. The dominant cation for two samples is calcium; there is no dominant cation for the remainder of the samples. Data plots closest to a calcium cation type. Sulfate is the major anion. The water is calcium sulfate type. TDS ranges from 946 mg/l to 2250 mg/l, well above the secondary MCL for drinking water. Groundwater samples from all thirteen wells are above the secondary MCL for drinking water for sulfate (SO_4^{2-}) and water from two wells is above the secondary MCL for manganese. A water sample from one well was analyzed for Title 22 metals. All Title 22 metals are below the primary MCL for drinking water. Water quality tends to become poorer to the south east portion of the basin in the vicinity of the Oak Ridge fault. Figure 3-11 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the Fillmore Basin.

Water samples from all the wells sampled in the Fillmore, Santa Paula and Piru Basins were compared in a piper diagram, Figure E-15. The piper diagram shows low variability; the data from the three is very similar and the water type for all is calcium sulfate.



Aerial photo showing the extent of the Fillmore groundwater basin.

FILLMORE BASIN

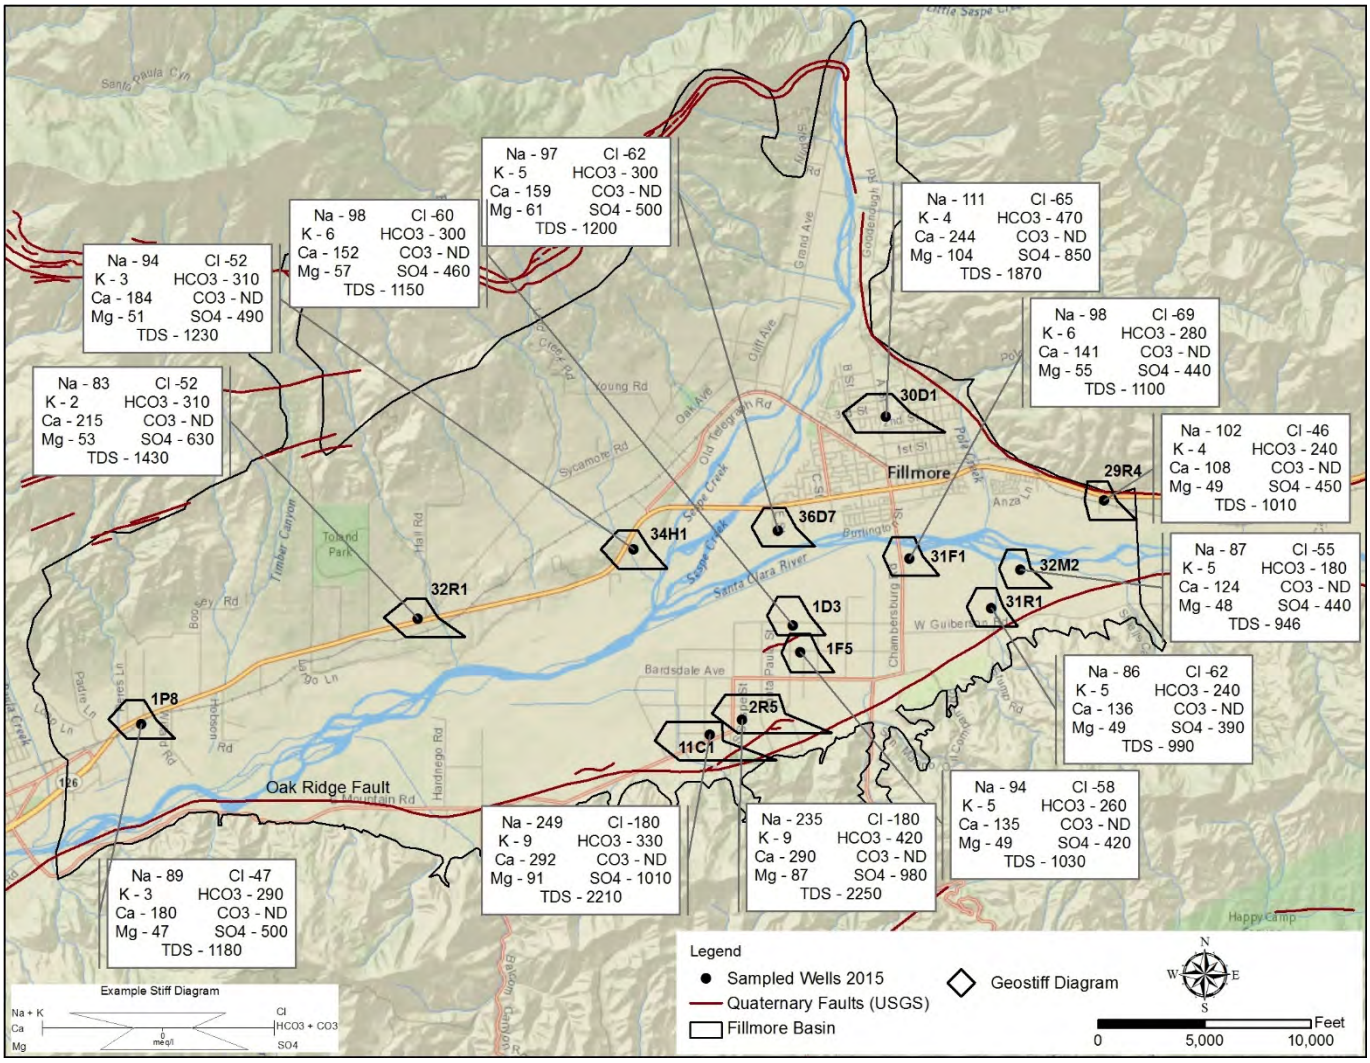


Figure 3-11: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams.

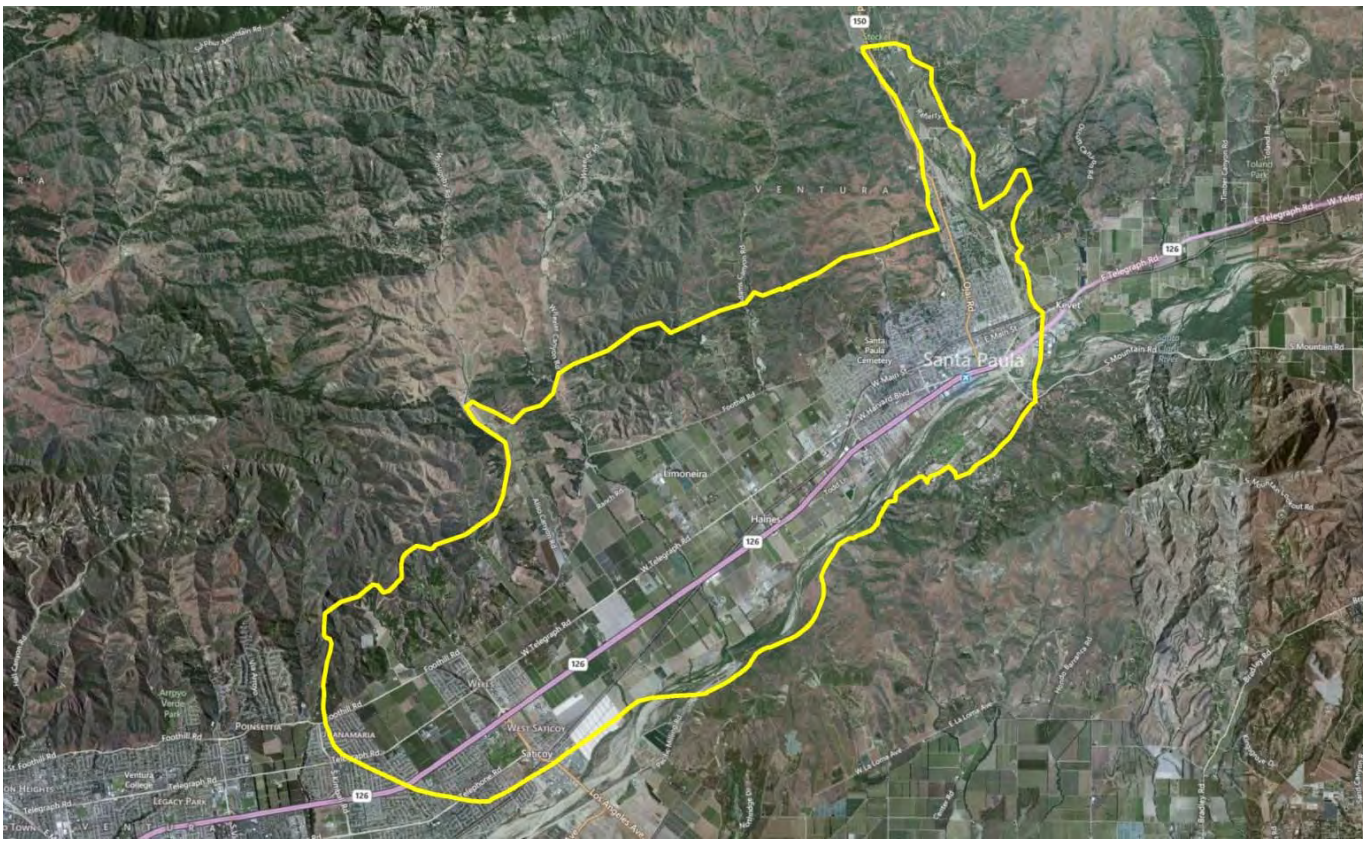
3.2.3 - Santa Paula Basin

The Santa Paula Basin is a court adjudicated groundwater basin. In an effort to prevent overdraft, a June 1991 judgment ordered the creation of the Santa Paula Basin Pumpers Association (SPBPA). The SPBPA regulates extractions in the Santa Paula Basin. The judgment stipulated an allotment of 27,000 acre-feet per year could be pumped from the basin. Water quality in the basin has not changed substantially since 2007. The depth to the water bearing material is 65 to 160 feet. There are approximately 283 water supply wells in the Santa Paula Basin; 152 are active. Figure E-13, piper diagram, shows no significant change in the water quality since the previous sampling round. Calcium is the dominant cation in one sample; the remainder have no dominant cation. Sulfate is the dominant anion. The water is calcium sulfate type. TDS concentrations range from 1010 mg/l to 2610 mg/l; all above the current secondary MCL for drinking water. Six water samples have concentrations above the secondary MCL for sulfate, five have manganese above the secondary MCL and one is above the secondary MCL for iron. Two water samples were analyzed for Title 22 metals. All Title 22 metals are below the primary MCL for drinking water. Figure 3-12 shows approximate well location and concentrations of total dissolved solids (TDS), sodium (Na^{+}), potassium (K^{+}), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^{-}), bicarbonate (HCO_3^{-}), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the well sampled in the Santa Paula Basin.

Figure E-15, piper diagram, compares water samples from the up-gradient Piru and Fillmore Basins to the Santa Paula Basin. The water chemistry is similar.



Aerial photo showing the extent of the Santa Paula groundwater basin.

SANTA PAULA BASIN

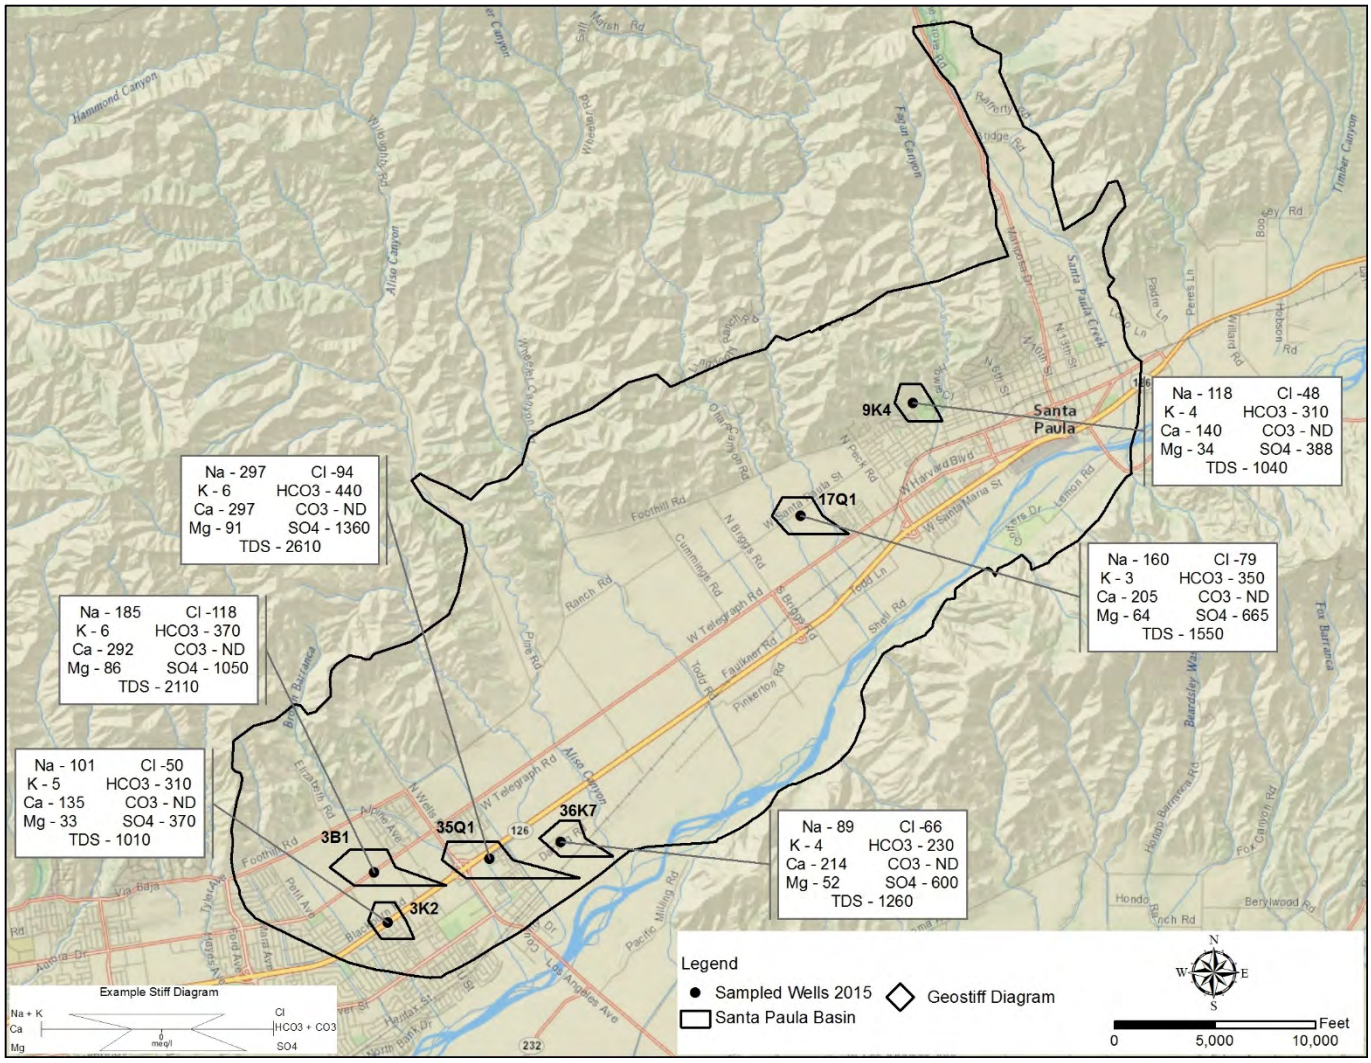


Figure 3-12: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams.

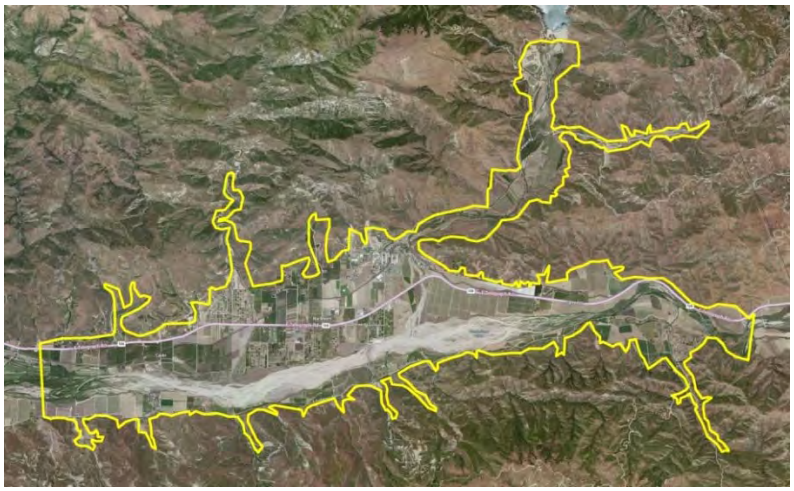
3.2.4 – Piru Basin

The Piru Basin groundwater recharge is principally from precipitation, releases of water by United Water Conservation District from Lake Piru, and the Santa Clara River. Flow from the Santa Clara River enters the basin from the east and carries discharges from wastewater treatment plants and urban and stormwater runoff from Los Angeles County. There are approximately 190 water supply wells in the Piru Basin; 151 are active. Depth to the main water bearing material is approximately 30 to 90 feet. The Los Angeles Regional Water Quality Control Board (LARWQCB) has adopted a Basin Plan Amendment that includes a Total Maximum Daily Load (TMDL) of 117 mg/l for chloride (Cl^-) in surface water and 150 mg/l in groundwater for the stretch of the Santa Clara River in Ventura County east of Piru Creek.

Fifteen wells were sampled in the Piru Basin during this round of sampling. None of the groundwater sampled has a chloride (Cl^-) concentration above the chloride TMDL. The piper diagram, Figure E-14, shows moderate variability in water quality of the wells sampled this year. There is no dominant cation for 14 samples; calcium is the dominant cation for the remaining sample and the data plots closest to the calcium cation type. There is no dominant anion for three of the samples; sulfate is the dominant anion for the remainder. The water is calcium sulfate type. The TDS concentration of the water sampled this season varies from 894 to 2820 mg/l; all wells above the secondary MCL for drinking water; three wells have concentrations significantly above 2000 mg/l. Water samples from all fifteen wells have sulfate (SO_4^{-2}) concentrations greater than the secondary MCL for drinking water, five have manganese (Mn) concentrations greater than the secondary MCL, and one sample has an iron (Fe^+) concentration above the MCL. Figure 3-13 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}).

Water samples from six wells were analyzed for Title 22 metals. One well has lead (Pb) above the Primary MCL for drinking water. One well located south of Highway 126 has consistently been found to have selenium levels that exceed the primary MCL for drinking water of 0.05 mg/l (50 µg/l). Elevated selenium concentrations occur in those wells perforated in the interval between approximately 125 to 250 feet below ground surface. A well located north of Highway 126 and perforated at a similar elevation does not have high selenium. Owners of the wells have been notified by Ventura County Environmental Health Department about possible adverse health effects from ingestion of water containing selenium.

Radiochemistry analysis was completed on water from one of the wells. Gross alpha was below the primary MCL for drinking water.



Aerial photo showing the extent of the Piru groundwater basin.

PIRU BASIN

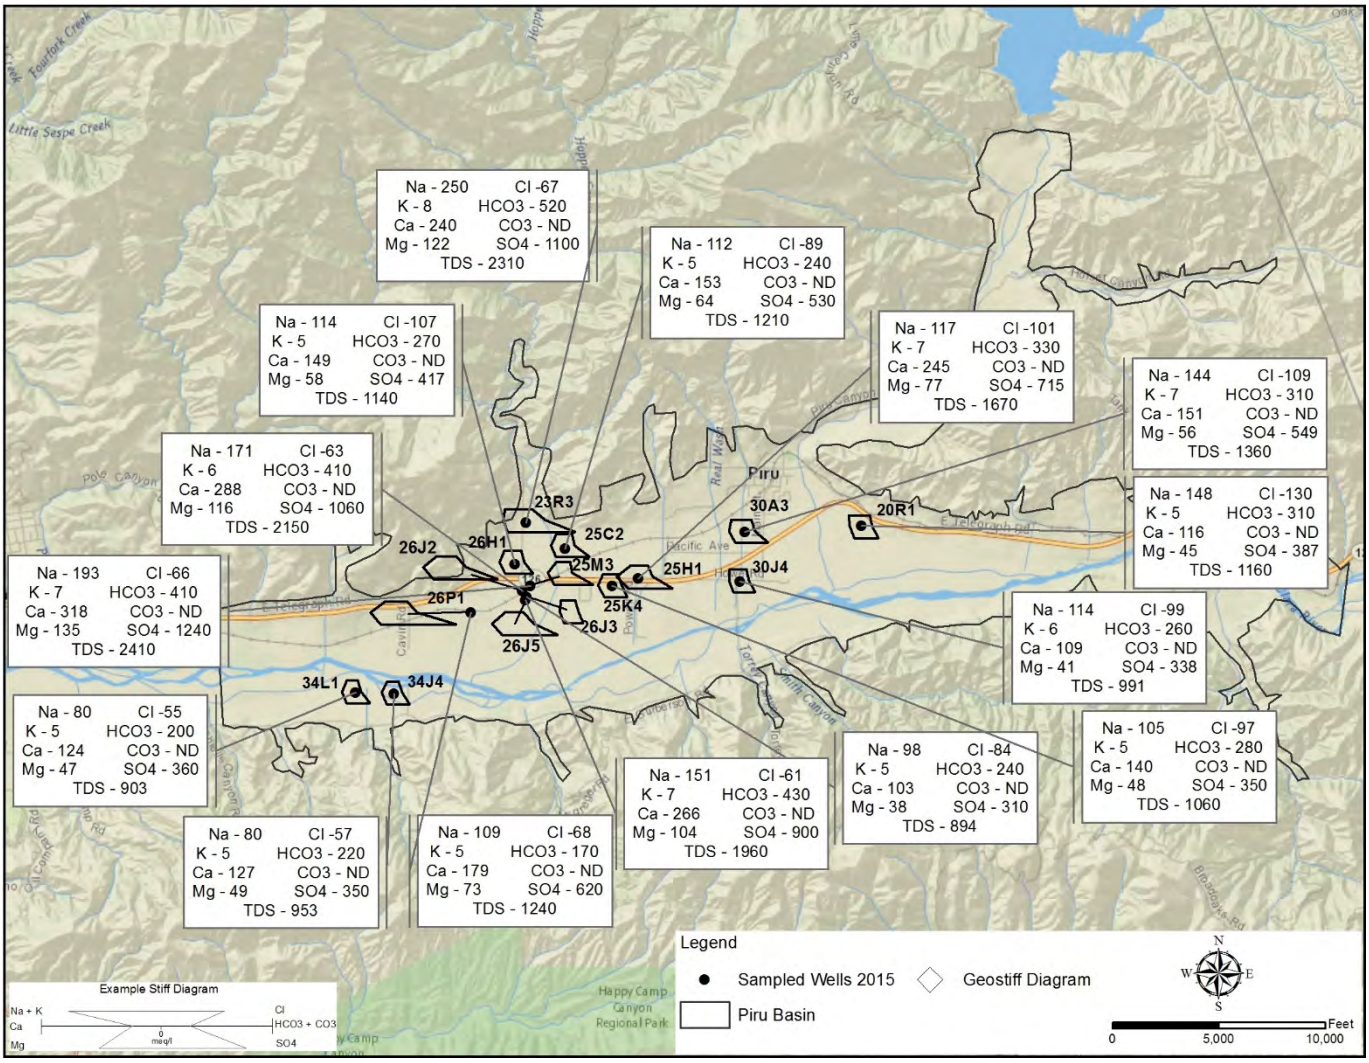


Figure 3-13: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams.

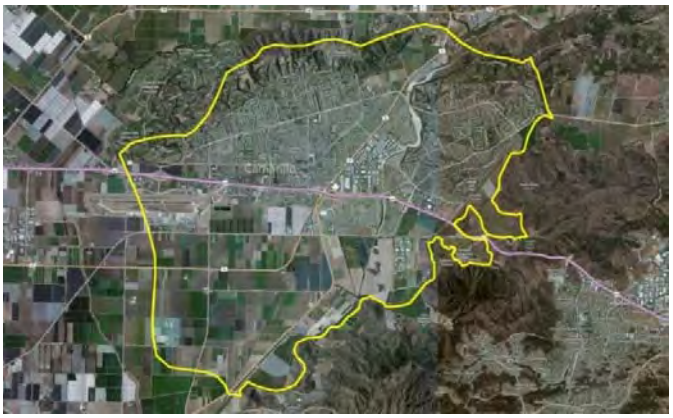
3.2.5 - Pleasant Valley Basin

In the Pleasant Valley Basin groundwater quality can vary greatly throughout the basin. The upper-most groundwater bearing unit at 35 to 60 feet is not used because the water quality is very poor. Permeable lenses of alluvial sands, gravels, silts, and clays of recent to Upper Pleistocene age that vary in thickness from a few feet to several hundred feet are equivalent to but not connected with the Oxnard Aquifer and are referred to here as the Upper zone. Depth to the main water bearing unit is approximately 400 to 500 feet. This deeper zone is referred to in this section as the Lower Zone. It is made up of marine sands and gravels of the lower-most member of the early Pleistocene San Pedro Formation and is known as the Fox Canyon Aquifer. The Grimes Canyon aquifer underlies the Fox Canyon aquifer at depths below 1000 feet and is penetrated by only the deepest wells. There are approximately 332 water supply wells in the Pleasant Valley Basin; 91 are active. Eighteen wells were sampled during this round of sampling; three perforated in the Upper zone and 15 perforated in the Lower zone.

The piper diagram, Figure E-16, shows a comparison of the wells based on whether the well is perforated in the upper zone or lower zone. Wells perforated in the upper zone tend to have higher concentrations of sulfate (SO_4^{2-}) than those in the lower zone. The piper diagram shows moderate variability in water quality of the wells in the lower zone and low variability for the wells in the upper zone. Water from the Upper zone wells show calcium (Ca^{+}) is the dominant cation for one of the samples and the remaining two samples have no dominant cation but plot very close to the calcium (Ca^{+}). Sulfate (SO_4^{2-}) is the dominant anion. The water in the Upper zone is calcium sulfate type. Water from the lower zone wells show sodium (Na^{+}) is the dominant anion for one well, and there is no dominant anion for the remainder. Sulfate (SO_4^{2-}) is the dominant anion for five samples and there is no dominant anion for the remaining ten samples but the data plots close to the sulfate (SO_4^{2-}) type. The water in one sample is sodium sulfate type; the remainder are calcium sulfate type.

TDS concentrations for all water samples (upper and lower zones) vary from 698 to 4340 mg/l. All nineteen wells sampled have TDS concentrations above the secondary MCL for drinking water. Fourteen of the wells have sulfate (SO_4^{2-}) concentrations above the secondary MCL for drinking water. Five water samples have iron (Fe) concentrations above the secondary MCL for drinking water and six have manganese (Mn) concentrations above the secondary MCL. Chloride (Cl^{-}) concentrations are above 117 mg/l in water samples from fifteen wells. Samples from three wells have Cl^{-} concentrations above the secondary MCL for drinking water, but the LARWQCB Basin Plan indicates that agricultural beneficial uses are impaired when the concentration is above 117 mg/l. Water samples from seven wells were analyzed for Title 22 metals. Five wells have lead (Pb) above the primary MCL for drinking water. No other Title 22 metal was above the primary MCL. Figure 3-14 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^{+}), potassium (K^{+}), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^{-}), bicarbonate (HCO_3^{-}), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}).



Aerial photo showing the extent of the Pleasant Valley groundwater basin.

PLEASANT VALLEY BASIN

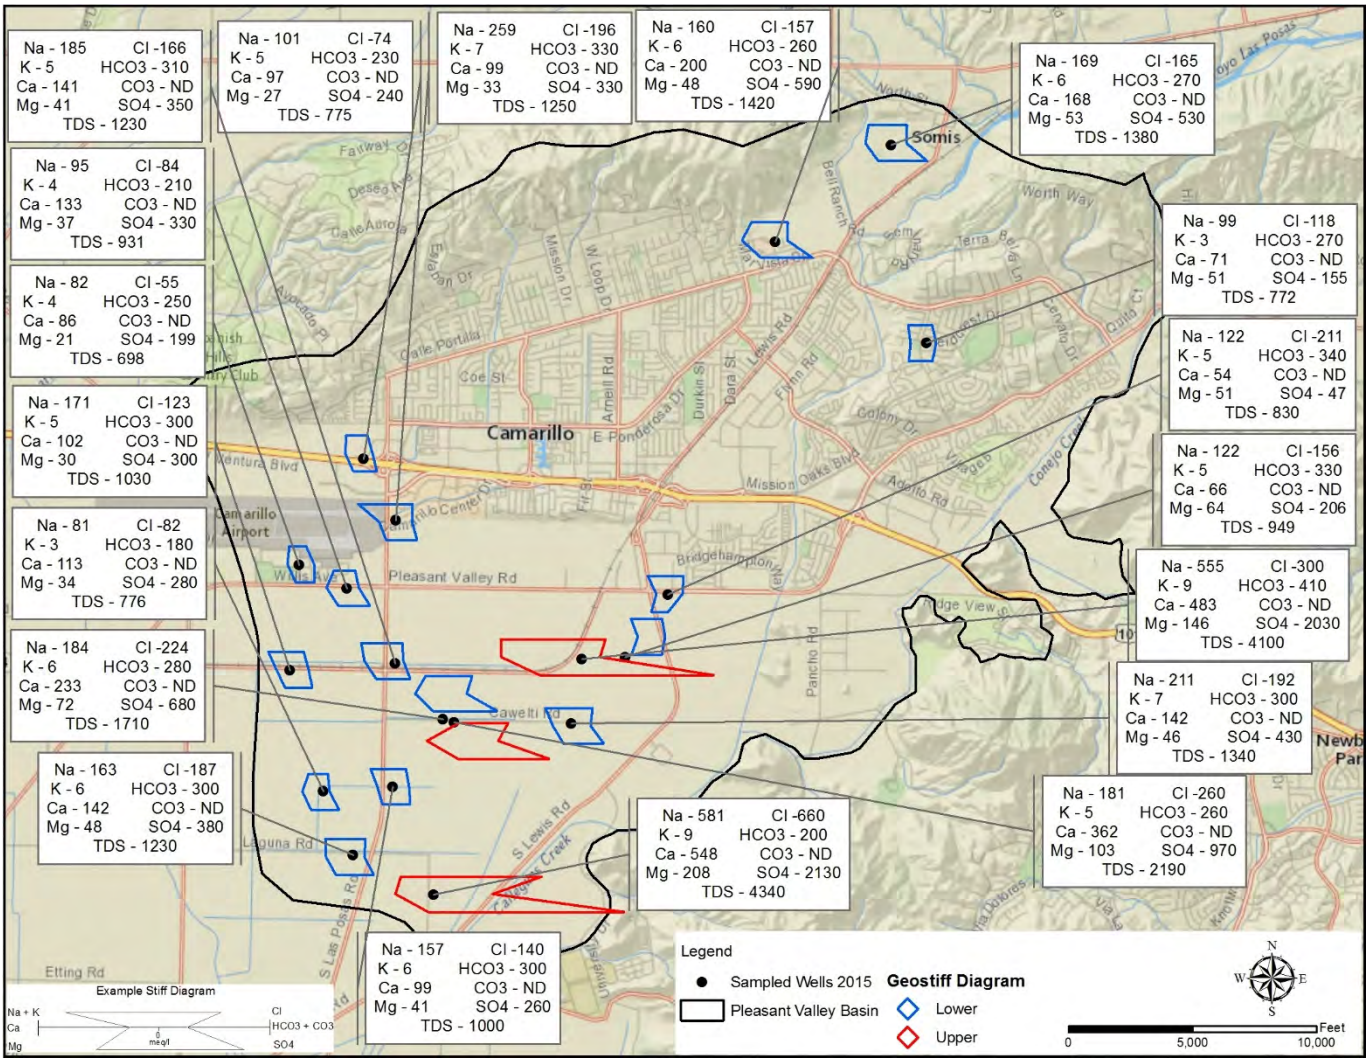


Figure 3-14: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams.

3.2.6 - Mound Basin

The Mound Basin water bearing units consist of Quaternary alluvium and the San Pedro Formation. These formations are divided into the Upper Aquifer System (UAS) and the Lower Aquifer System (LAS). The UAS consists of undifferentiated Holocene alluvium that make up the Oxnard aquifer and older Pleistocene alluvium that makes up the Mugu Aquifer. The alluvium consists of silts and clays with lenses of sand and gravel and reaches a maximum thickness of about 500 feet. The LAS consists dominantly of fine sands and gravels of the San Pedro Formation and extends as deep as 4,000 feet. The upper part of the San Pedro formation consists of variable amounts of clay, silty clay and sand. A series of inter-bedded water-bearing sands in this section are time equivalent to the Hueneme aquifer of the Oxnard Basin. The lower part of the San Pedro formation consists primarily of sand and gravel zones with layers of clay and silt and is known as the Fox Canyon aquifer in the Oxnard plain and extends into the Mound Basin. Groundwater is generally unconfined in the alluvium and confined in the San Pedro Formation. Historic water quality data for the basin shows that water quality is generally better in the lower zone but our data does not show that this year. Three of the five wells sampled this year are perforated in the LAS, much deeper than the other two. One of those wells has water quality that is significantly better than the other LAS wells. One of the shallow UAS wells has water quality that is similar to the deep wells and one well has significantly worse water quality.

There are approximately 78 water supply wells in the Mound Basin; 29 are active water supply wells. Figure E-17, piper diagram, shows low to moderate variability in water quality of all the wells sampled this year, LAS and UAS. Sodium is the dominant cation for one water sample and one sample plots close to the calcium type; there is no dominant cation for the remaining three water samples. Sulfate (SO_4^{2-}) is the dominant anion for all samples. One sample is sodium sulfate type and the remaining samples are calcium sulfate type.

TDS concentration for the wells sampled this year ranges from 1070 to 3000 mg/l; all above the secondary MCL for drinking water. Sulfate (SO_4^{2-}) concentration and manganese are greater than the secondary MCL for drinking water in all five wells sampled; iron is above the secondary MCL in three of the wells. Figure 3-15 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}).

Aerial photo showing the extent of the Mound groundwater basin.

MOUND BASIN

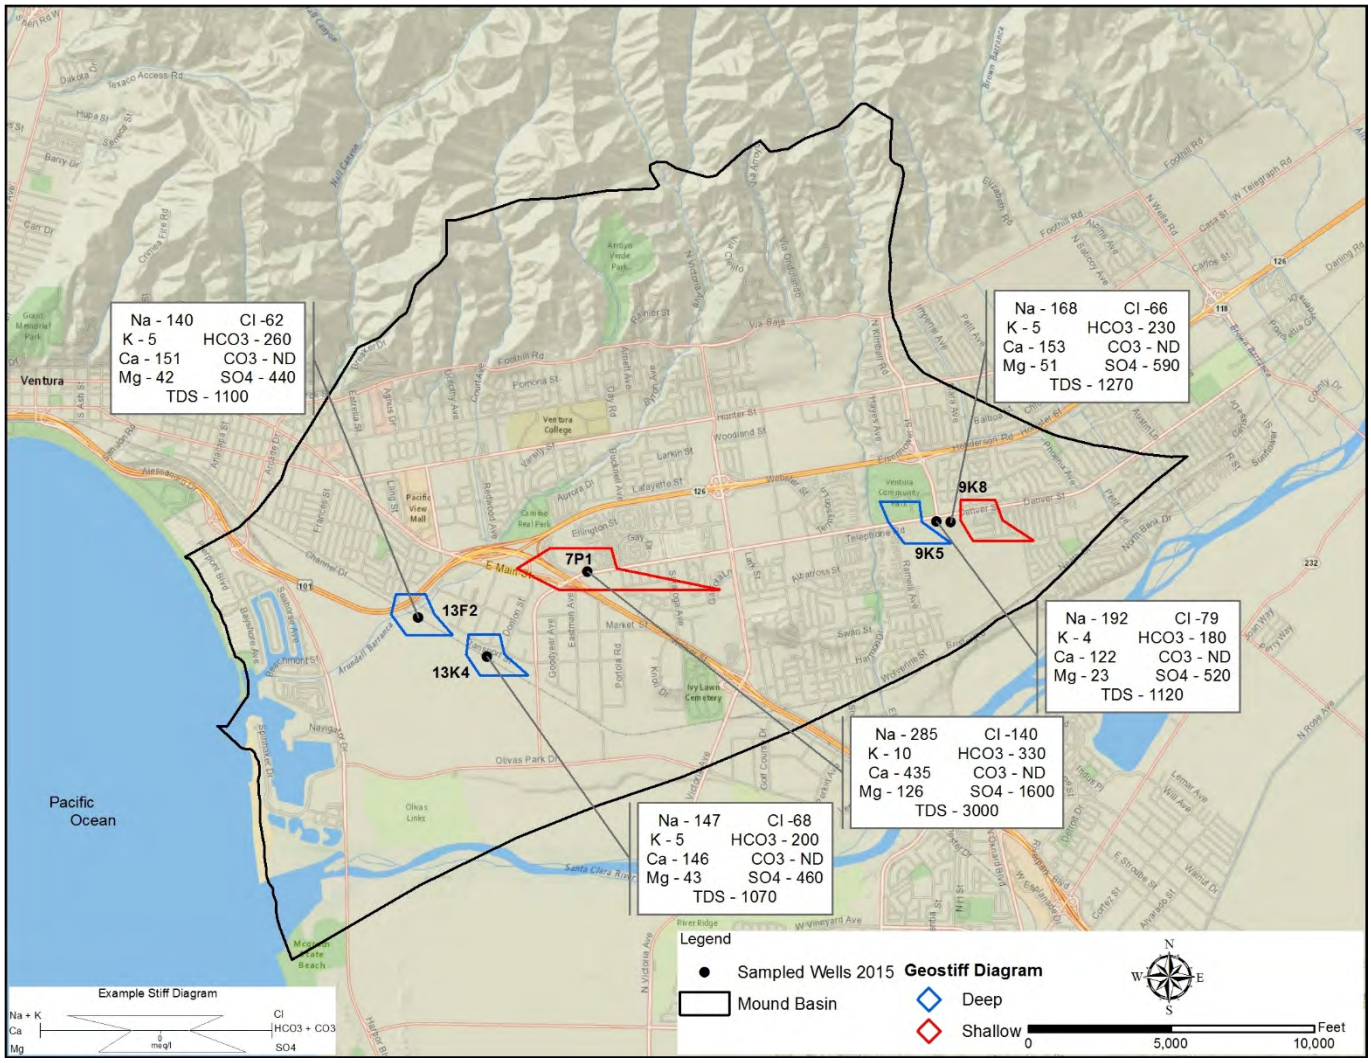

Figure 3-15: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagram.

3.2.7 - East Las Posas Basin

Water bearing material of the East Las Posas Basin consists of Recent and Pleistocene alluvial deposits of varying thickness. Water bearing material consists primarily of sand or a mixture of sand and gravel identified as the Fox Canyon Aquifer in this basin and is the basal member of the Pleistocene age, San Pedro Formation (Stokes, 1971). The Fox Canyon aquifer is generally considered to be confined in the East Las Posas Basin. However data indicates the Fox Canyon Aquifer receives recharge from leakage from aquifers located above it (FCGMA 2007 Basin Management Plan). The exact hydrogeologic connectivity is not well understood. Depth to the upper water bearing unit is approximately 120 to 150 feet and to the lower unit is approximately 530 to 580 feet. There are approximately 248 water supply wells in the East Las Posas Basin; 155 are active water supply wells.

Figure E-18, piper diagram, shows moderate variability in water quality of the wells sampled this year. Calcium is the dominant cation for nine of the wells sampled; there is no dominant cation for the remaining four wells. Sulfate (SO_4^{2-}) is the dominant anion for five of the wells; bicarbonate is the dominant anion for six of the wells sampled; and two wells have no dominant anion. The water in seven of the wells sampled is calcium sulfate type, six of the wells are calcium bicarbonate type. Of the thirteen wells sampled in the East Las Posas Basin, the three wells located in the southwest portion of the basin near the Arroyo Las Posas, have very different water chemistry from the other nine. TDS and sulfate are above the secondary MCL for drinking water in all three southwestern wells and they all have elevated chloride (Cl^-), not above the drinking water MCL but above the level that could be harmful to crops. The remainder of the wells have good water quality with TDS ranging between 261 and 805 mg/l. Water from three wells was analyzed for Title 22 metals. Lead (Pb) concentration is above the primary MCL for drinking water in one sample. No other Title 22 metal was above the primary MCL for drinking water.

Figure E-21, piper diagram, shows a comparison of East, West, and South Las Posas water chemistry. There is moderate variability in the water quality of the combined basins. The South Las Posas basin has less variability but fewer wells were sampled in that basin. The majority of the water samples from all three basins is in two main groups, those with sulfate (SO_4^{2-}) as the dominant anion, calcium sulfate type and those with no dominant anion but which plot near the bicarbonate type, calcium bicarbonate type. The water chemistry of East and West Las Posas Basins is fairly similar, even though, based on the sharp change in water level between the East Las Posas and West Las Posas basins, the degree of hydrologic connection appears to be limited. Figure 3-16 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}).

Aerial photo showing the extent of the East Las Posas groundwater basin.

EAST LAS POSAS BASIN

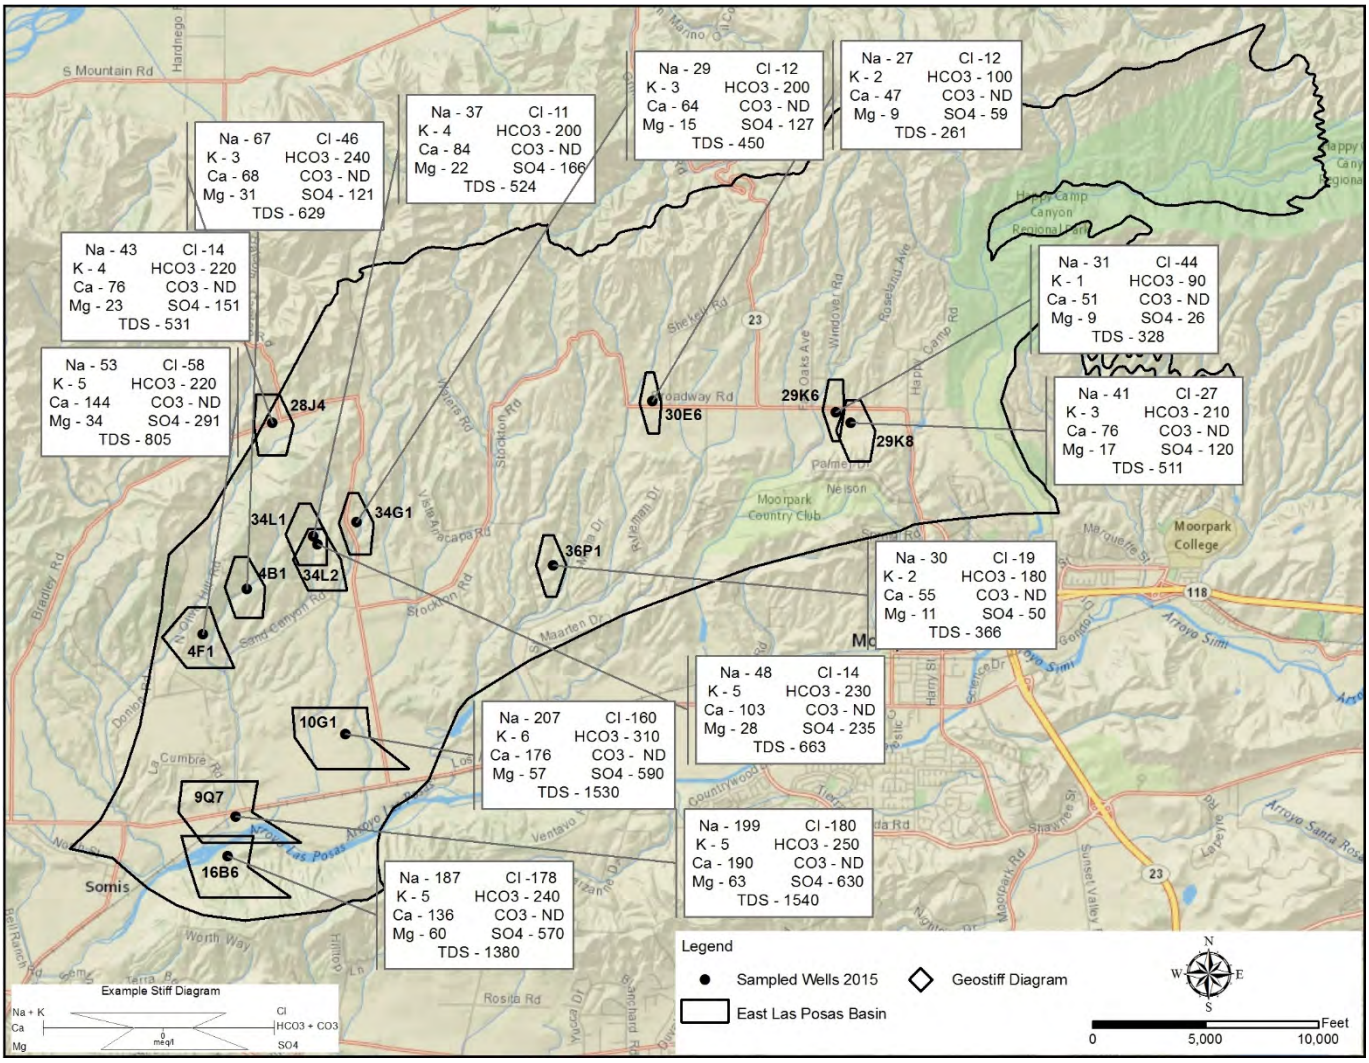

Figure 3-16: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents.

3.2.8 - West Las Posas Basin

There are approximately 114 water supply wells in the West Las Posas Basin; 63 of those are active wells. Figure E-19, piper diagram, shows moderate variability in water quality of the wells sampled this year. Calcium (Ca^{2+}) is the dominant cation for two of the samples and there is no dominant cation for the remainder. Bicarbonate (HCO_3^-) is the dominant anion for two of the wells sampled; sulfate (SO_4^{2-}) is the dominant anion for six of the wells and four wells have no dominant anion but plot close to the bicarbonate (HCO_3^-) anion type. The water in ten wells is calcium sulfate type and the remaining two wells are calcium bicarbonate type.

TDS is above the secondary MCL for drinking water in eleven of the wells sampled in the West Las Posas Basin this year; ranging from 300 to 1380 mg/L. One well has a nitrate concentration above the primary MCL for drinking water. Five wells have sulfate (SO_4^{2-}) above the secondary MCL; six have manganese concentrations above the MCL. Four wells have iron concentration above the MCL for drinking water, one over 28 times the MCL. The piper diagram also shows water quality data for one well, 13A1, that is just outside the mapped basin boundary. The chemistry of this well is very similar to that of the wells inside the mapped boundary. It is most similar to the well to the northwest, 36Q1, which has a water level at approximately the same elevation. Water from four wells was analyzed for Title 22 metals. Lead (Pb) concentration is above the primary MCL for drinking water in two samples. No other Title 22 metal was above the primary MCL for drinking water. Figure 3-17 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the West Las Posas Basin.

Aerial photo showing the extent of the West Las Posas groundwater basin.

WEST LAS POSAS BASIN

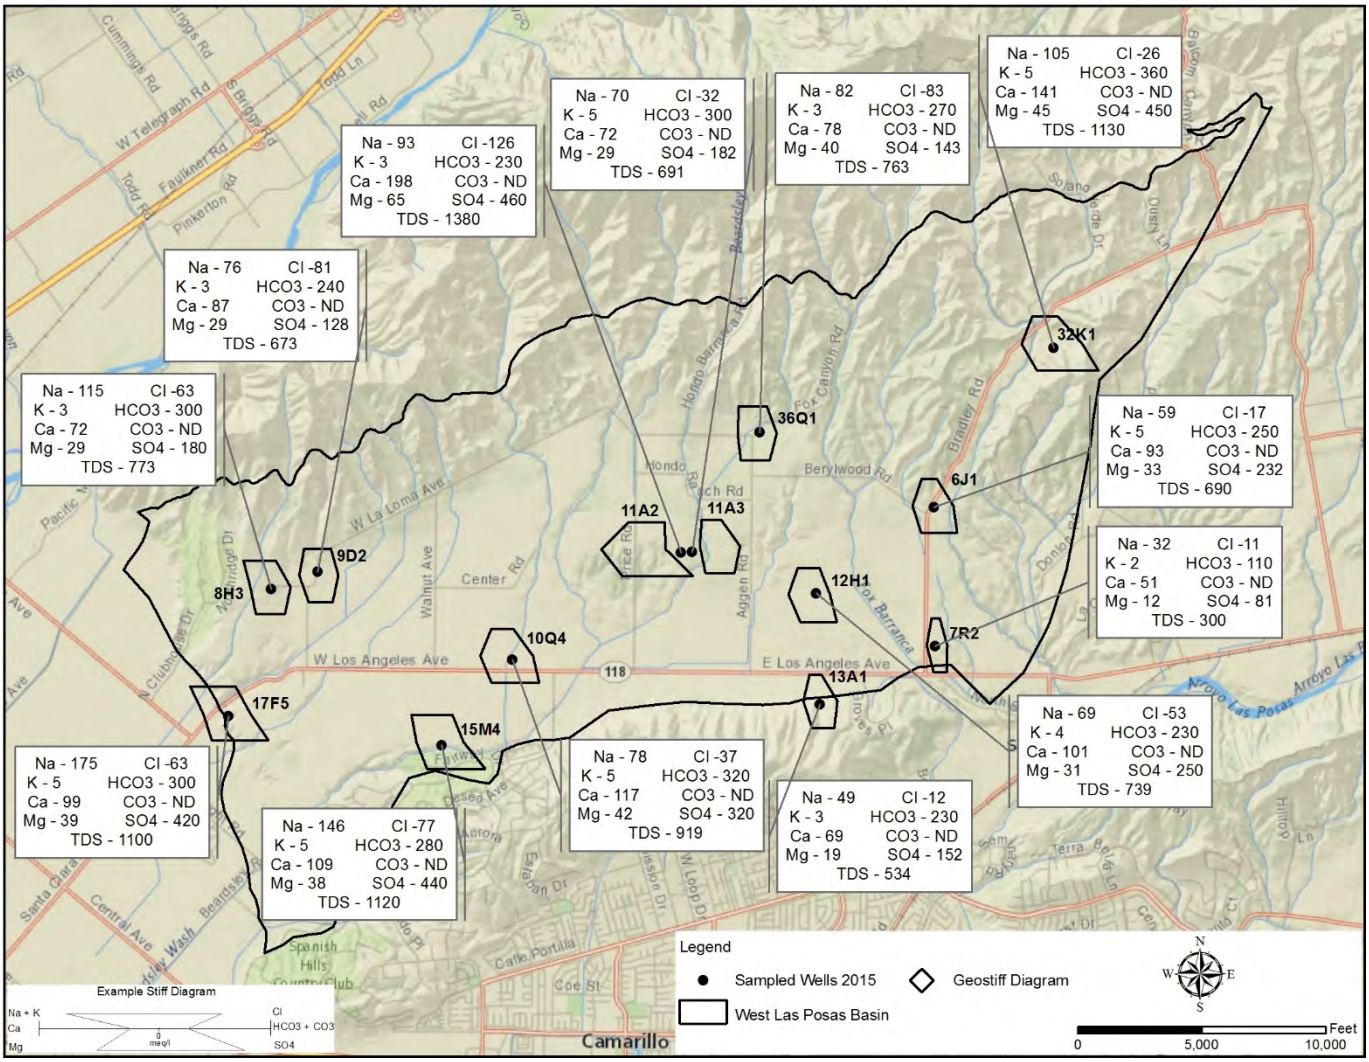

Figure 3-17: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams.

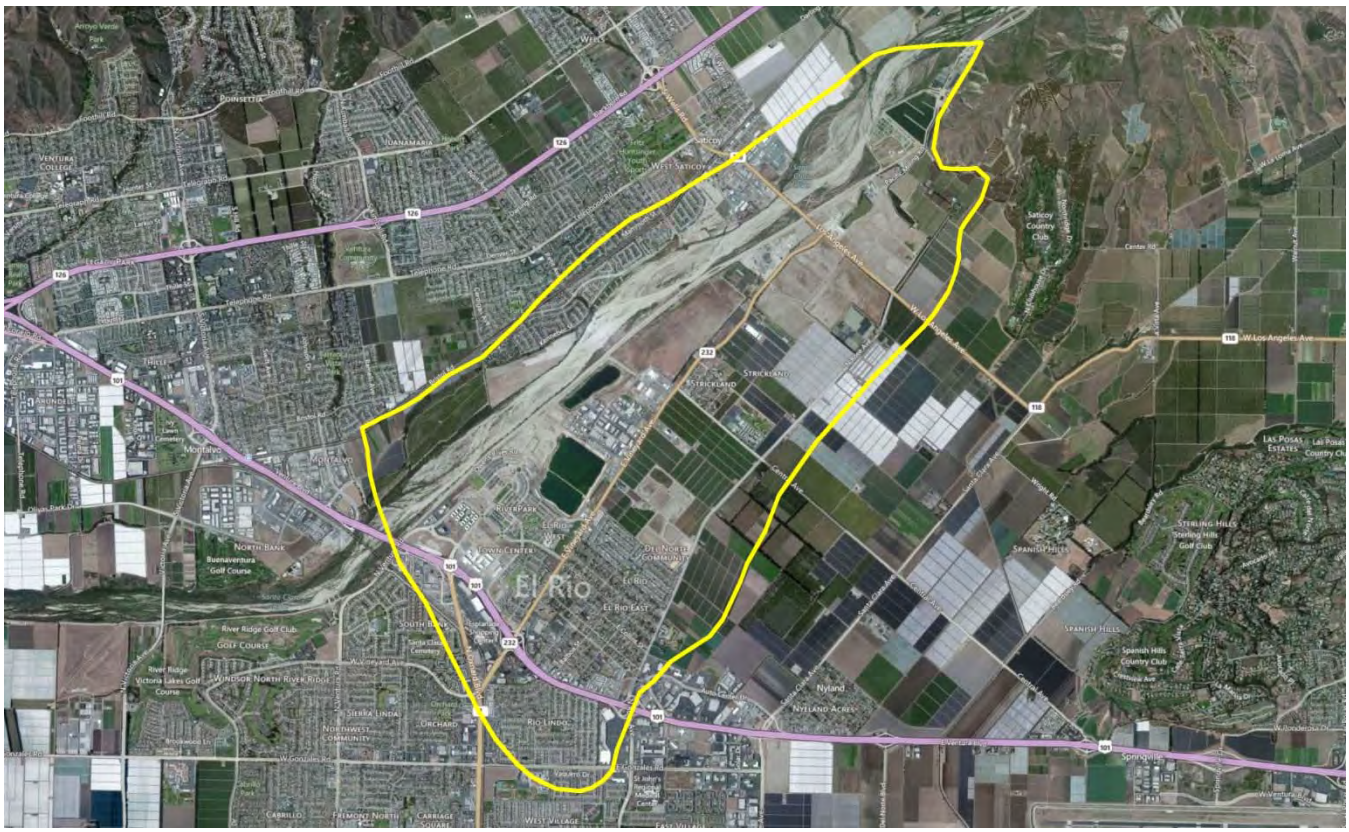
3.2.9 – Oxnard Plain Forebay Basin

The Oxnard Plain Forebay Basin is the principal recharge area for the Upper and Lower Aquifer Systems of the Oxnard Plain Pressure Basin. Approximate depth to the water bearing unit is 25 to 50 feet. There are approximately 304 water supply wells in the Oxnard Plain Forebay Basin; 105 are active wells. The Oxnard Plain Forebay generally has acceptable water quality except for the southern portion where high nitrate concentrations are common. The area to the north is predominantly agricultural with a few residential areas that still rely on individual septic systems. Three wells in the Oxnard Plain Forebay Basin were sampled this season; two in the Upper Aquifer System and one in the Lower Aquifer System. Figure E-22, piper diagram, shows low variability in water quality of all three wells sampled this year. The piper diagram shows there is a small difference between the upper and lower Forebay aquifers. There is no dominant cation type but the three samples plot close to the calcium type; sulfate (SO_4^{2-}) is the dominant anion. The water in all three samples is calcium sulfate type. The piper diagram, Figure E-23, shows that the wells sampled have very similar chemistry to that of the UAS of the Oxnard Plain Pressure Basin.

All three wells sampled have TDS and sulfate concentrations above the secondary MCL for drinking water and one had manganese (Mn^{+}) concentration above the MCL. One of the wells sampled this year has a nitrate concentration above the MCL for drinking water. Water from one well was analyzed for Title 22 metals. None of the Title 22 metals was above the primary MCL for drinking water. Figure 3-18 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^{+}), potassium (K^{+}), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^{-}), bicarbonate (HCO_3^{-}), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the Oxnard Forebay Basin.



Aerial photo showing the extent of the Oxnard Plain Forebay groundwater basin.

OXNARD FOREBAY BASIN

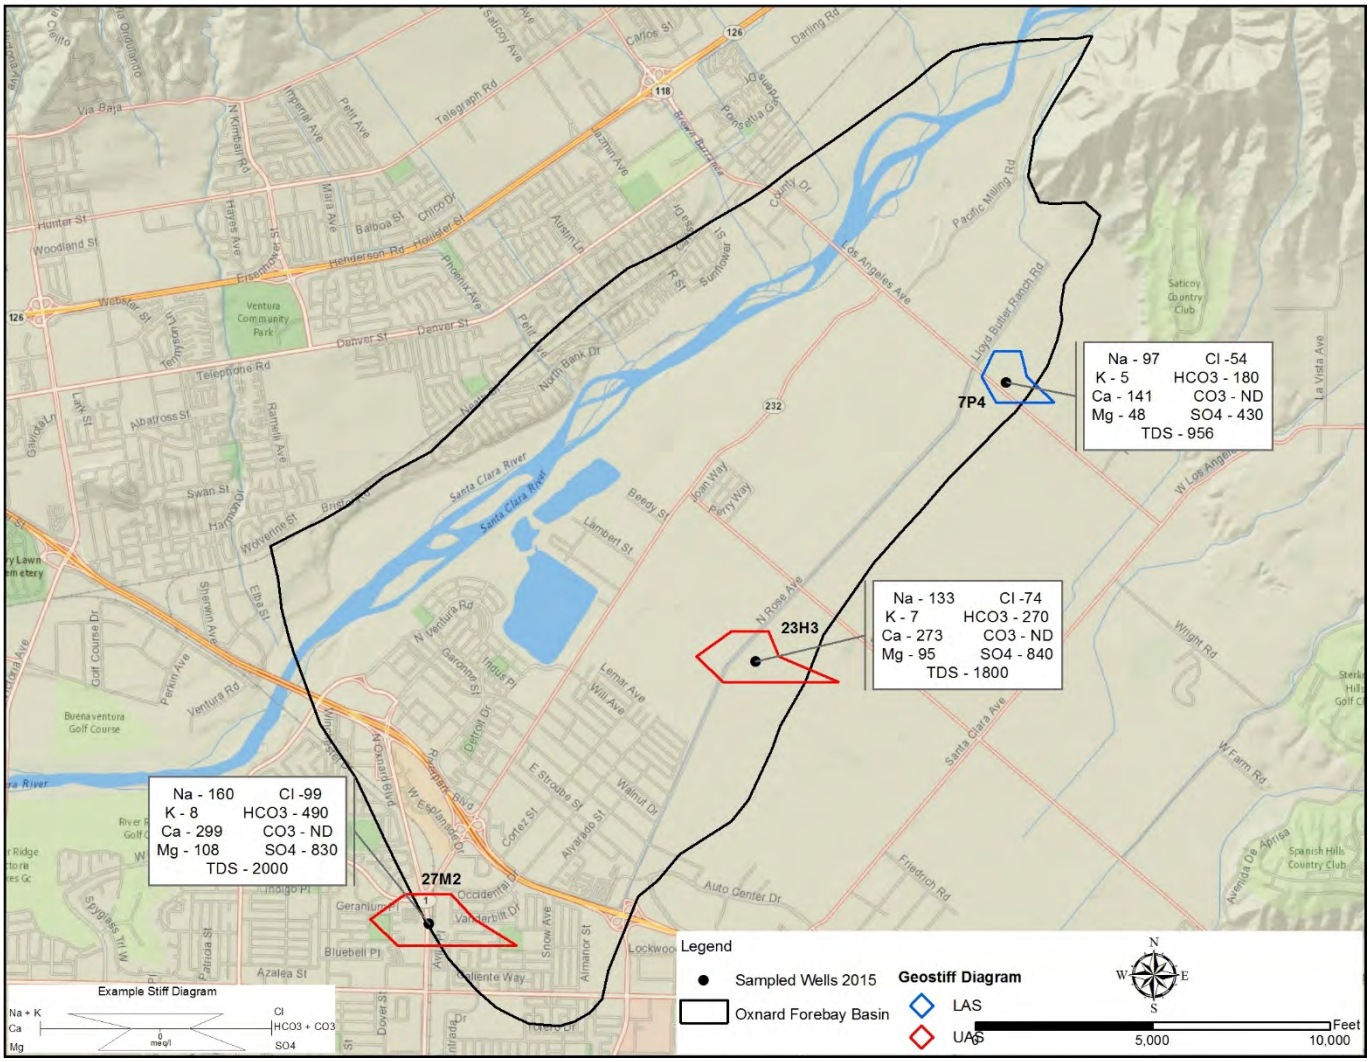


Figure 3-18: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams.

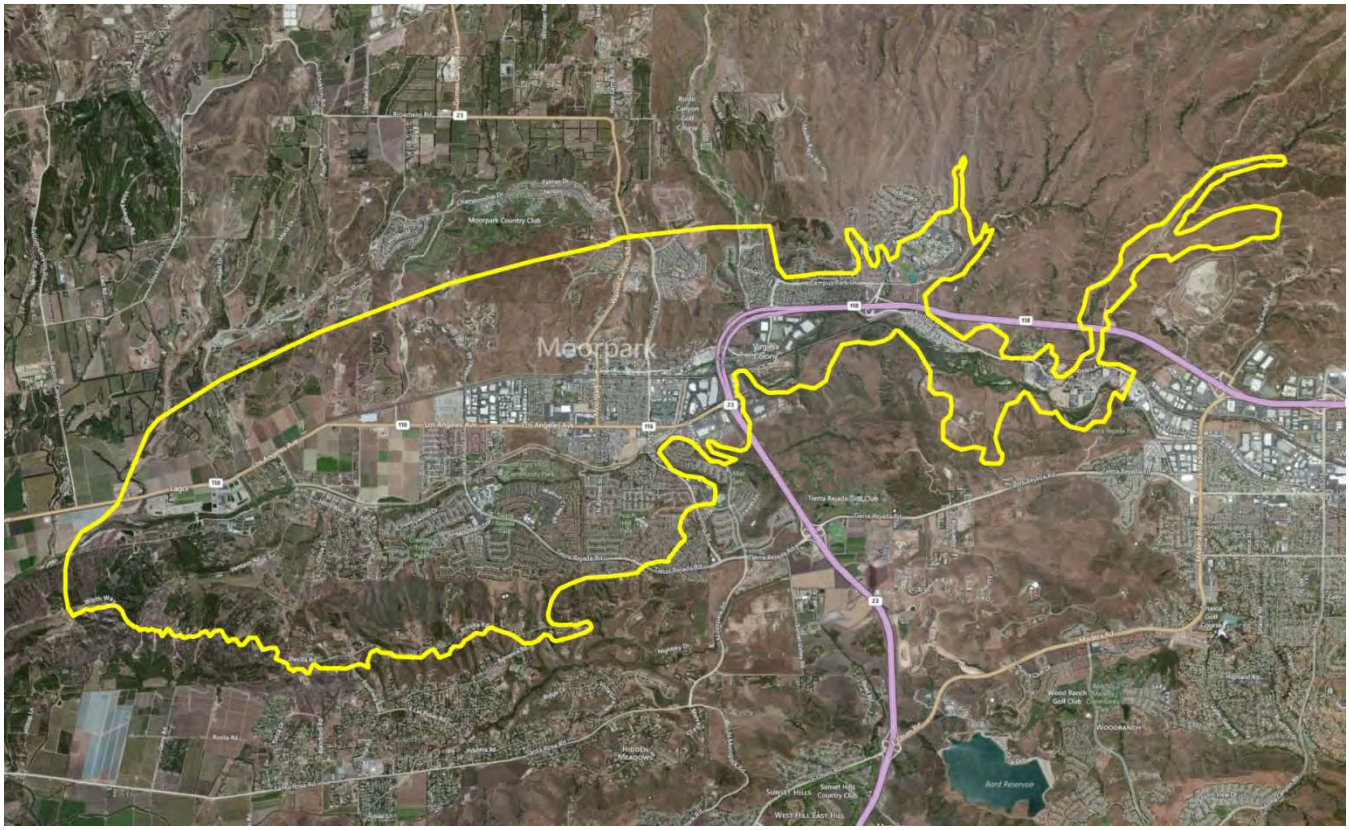
3.2.10 - South Las Posas Basin

The upper water bearing unit in the South Las Posas Basin is approximately 25 to 50 feet below ground surface and the lower is at approximately 350 to 500 feet below ground surface. Generally, deeper wells perforated in the Fox Canyon aquifer tend to have better water quality than the upper unit, however that has changed some over the years. Well 07B02 is perforated much deeper than the other three wells sampled but the water chemistry is similar. There are approximately 171 water supply wells in the South Las Posas Basin; 28 are active. Figure E-20, piper diagram, shows low variability in water quality of the wells sampled this year. The dominant cation for one well is sodium; the remaining three samples have no dominant cation. Sulfate (SO_4^{2-}) is the dominant anion in all three samples. The water type of one well is sodium sulfate; the remainder of the wells are calcium sulfate type. The South Las Posas Basin has had no significant change in water quality over the past year. Water from all four wells sampled has TDS and sulfate SO_4^{2-} concentrations above the secondary MCL for drinking water and elevated chloride; not above the secondary MCL for drinking water (but high enough to be detrimental for some agricultural uses). No sample was analyzed for Title 22 metals. Water chemistry in the South Las Posas Basin is fairly consistent across the basin. A comparison of the East, West, and South Las Posas Basins is shown in the piper diagram, Figure E-21. Figure 3-19 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the South Las Posas Basin.



Aerial photo showing the extent of the South Las Posas groundwater basin.

SOUTH LAS POSAS BASIN

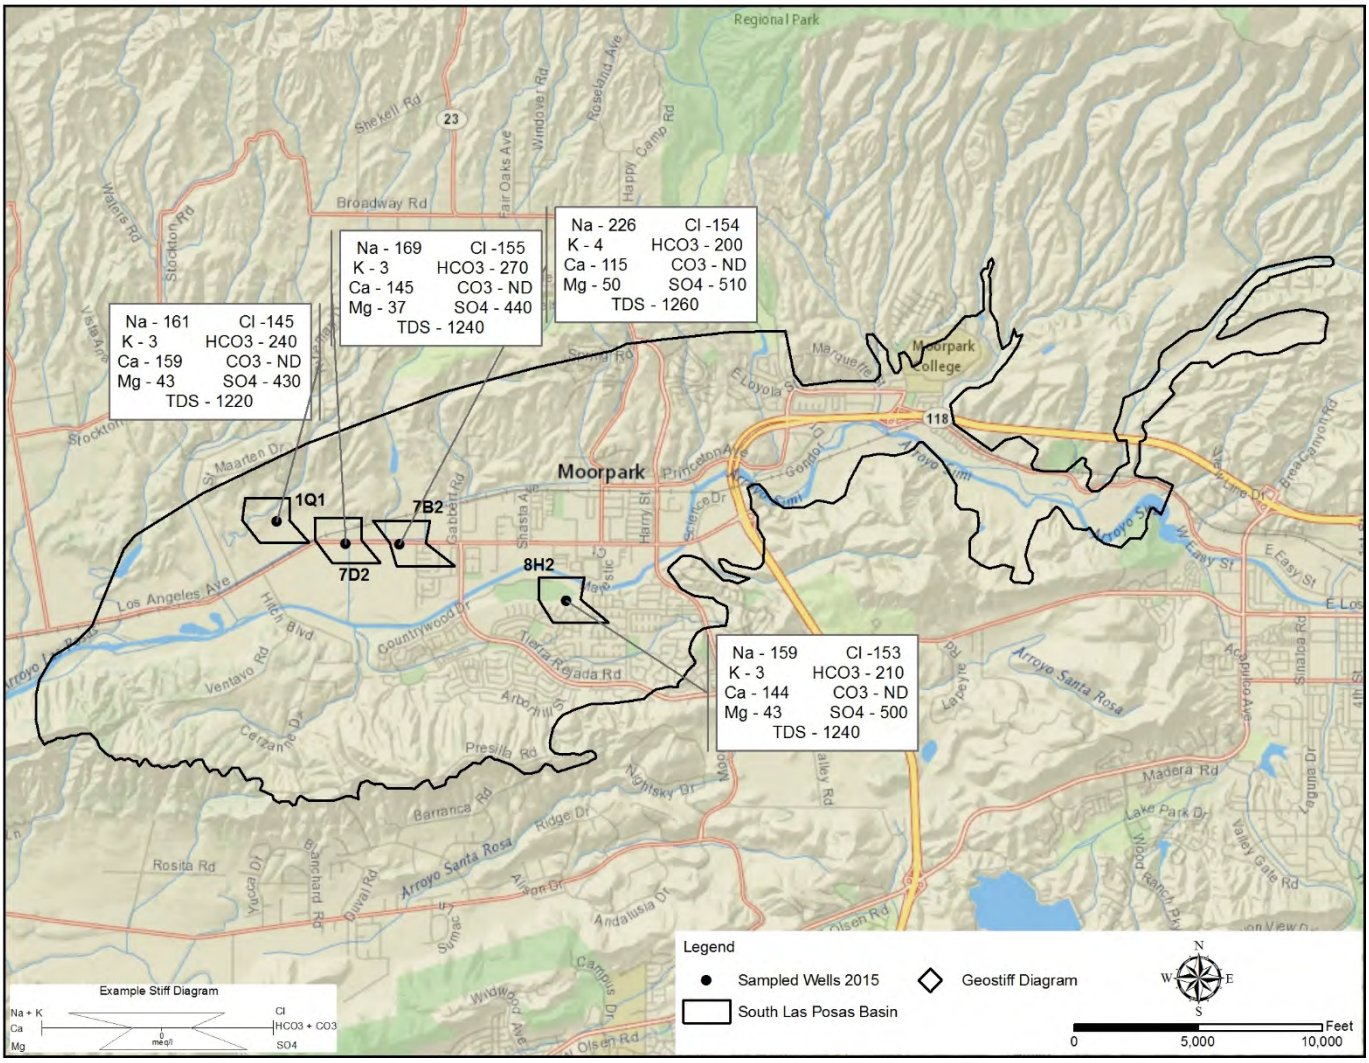


Figure 3-19: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams.

3.2.11 - Lower Ventura River Basin

The Lower Ventura River Basin has few remaining active water wells available for sampling. Depth to the water bearing unit is 3 to 13 feet below ground surface in the floodplain and deeper as the ground surface elevation increases towards the edges of the basin. There are approximately 32 water supply wells in the Lower Ventura River Basin; 17 are active wells. The piper diagram, Figure E-24, shows the water quality of the three wells sampled this year. There is no dominant cation or anion. The water type is calcium sulfate type. The wells sampled this year are located in river alluvium near the coast. Total dissolved solids and sulfate concentrations in all three wells are above the secondary MCL. Iron (Fe^{+}) is above the secondary MCL in one well and manganese (Mn^{+}) and chloride (Cl^{-}) are above the secondary MCL in two wells. Figure 3-20 shows the approximate well location and concentrations of total dissolved solids (TDS), sodium (Na^{+}), potassium (K^{+}), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^{-}), bicarbonate (HCO_3^{-}), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the Lower Ventura River basin. Piper diagram Figure E-26 shows a comparison of the chemistry between Upper and Lower Ventura River Basins.

Aerial photo showing the extent of the Lower Ventura River groundwater basin.

LOWER VENTURA RIVER BASIN

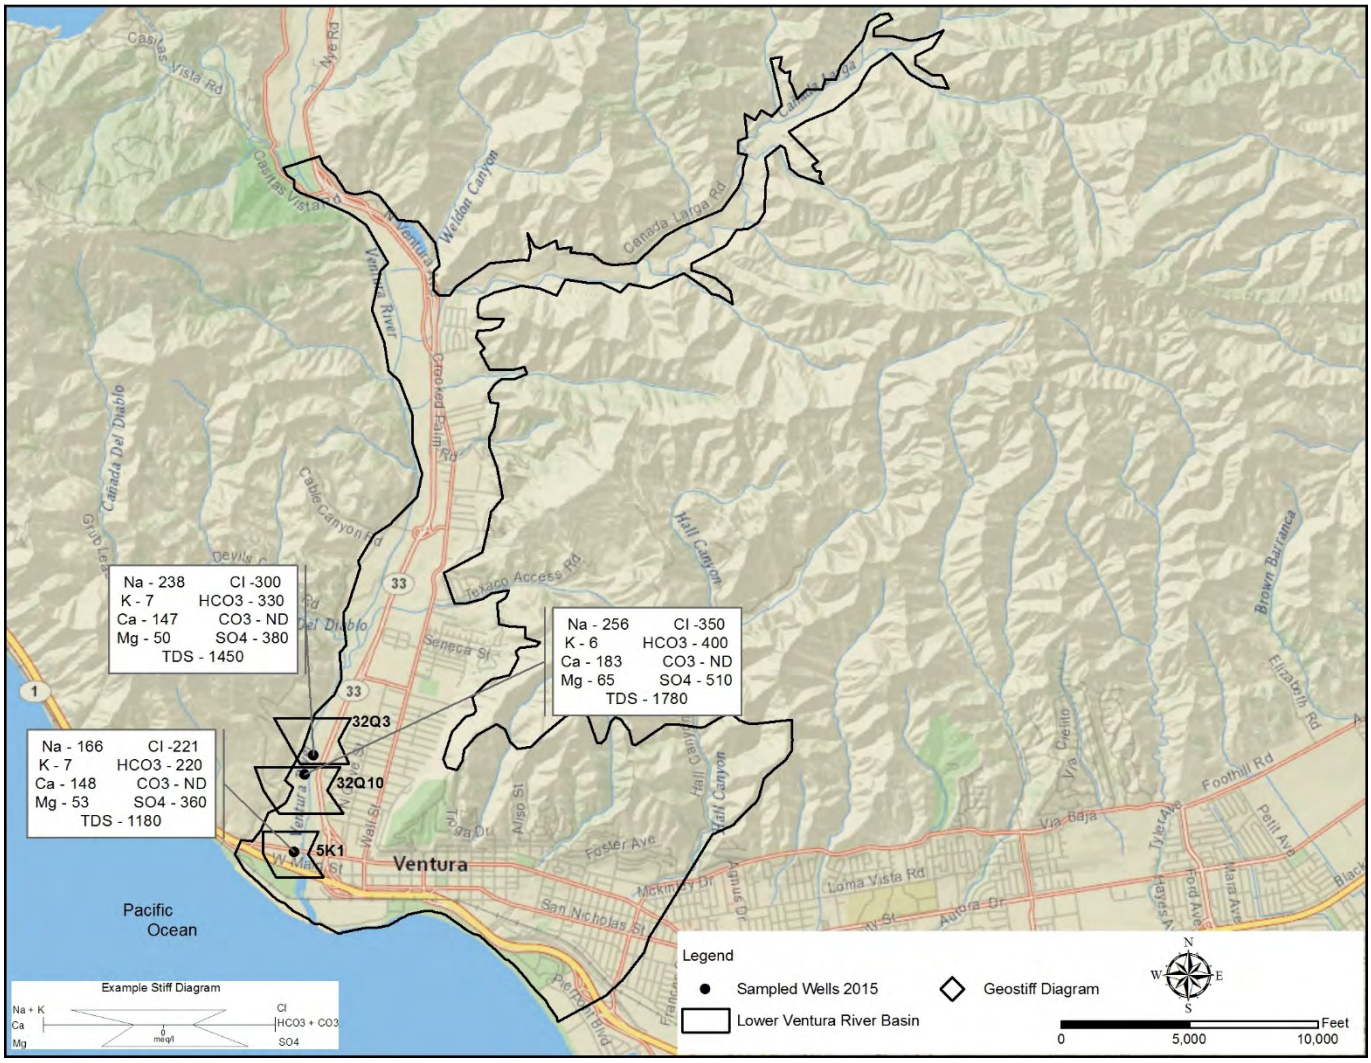

Figure 3-20: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams.

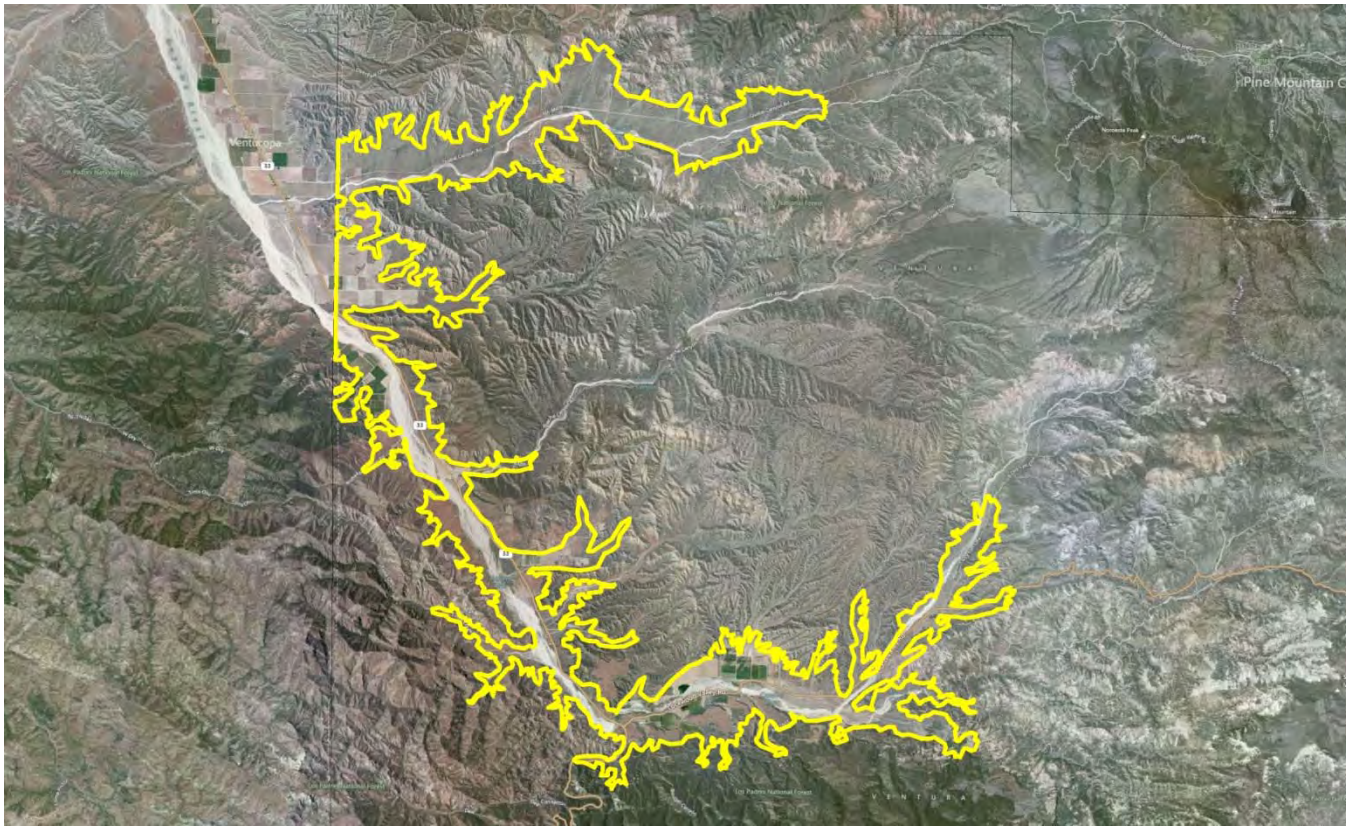
3.2.12 - Cuyama Valley Basin

The Cuyama Valley Basin is in a remote area in northwestern Ventura County. The aerial photo and the map in Figure 3-18 show only the portion of the basin that is in Ventura County. There are approximately 149 wells in the Cuyama Valley Basin; 112 are active water supply wells. Depth to the main water bearing unit varies between 40 to 170 feet below ground surface. Figure E-27, piper diagram, shows low variability in water quality of the wells sampled this year. Sodium (Na^+) is the dominant cation in the three samples; there is no dominant anion. All three samples are sodium bicarbonate type. The wells sampled this year have TDS above the secondary MCL for drinking water; no other constituent was elevated. Water samples from all three wells were analyzed for Title 22 metals. None of the Title 22 metals was above the primary MCL for drinking water. California Department of Water Resources Groundwater Bulletin No. 118 indicates groundwater quality has been deteriorating in some areas because of cycling and evaporation of irrigation water. All three wells sampled have good water quality but are located in the northern part of the basin where there is not as much irrigation. Figure 3-21 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the Cuyama Valley basin.



Aerial photo showing the extent of the Cuyama Valley groundwater basin.

CUYAMA VALLEY BASIN

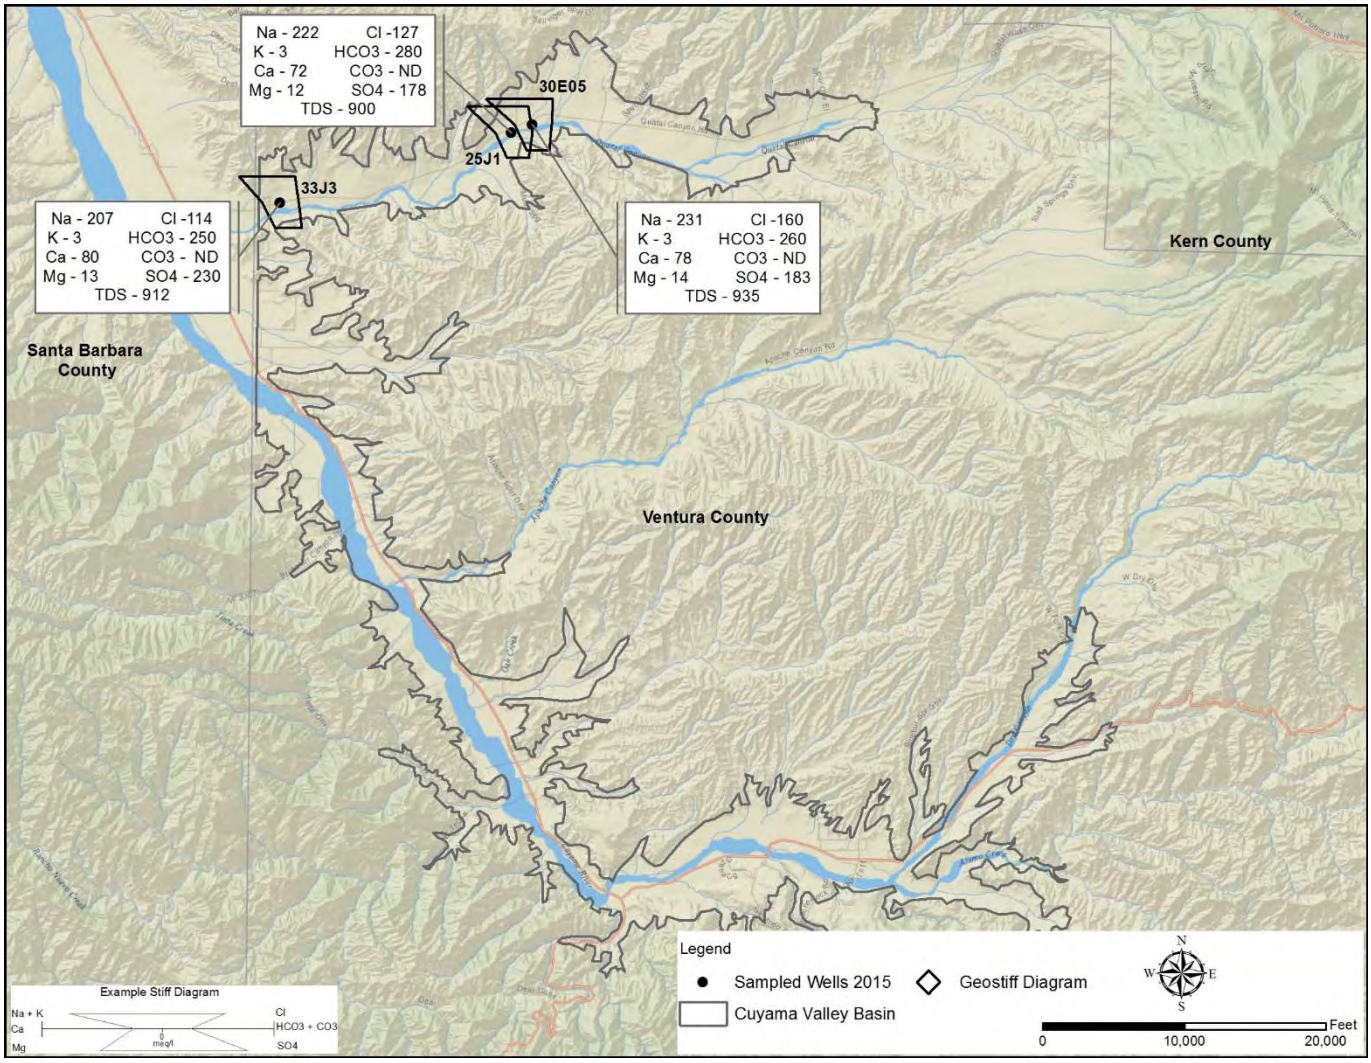


Figure 3-21: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagram.

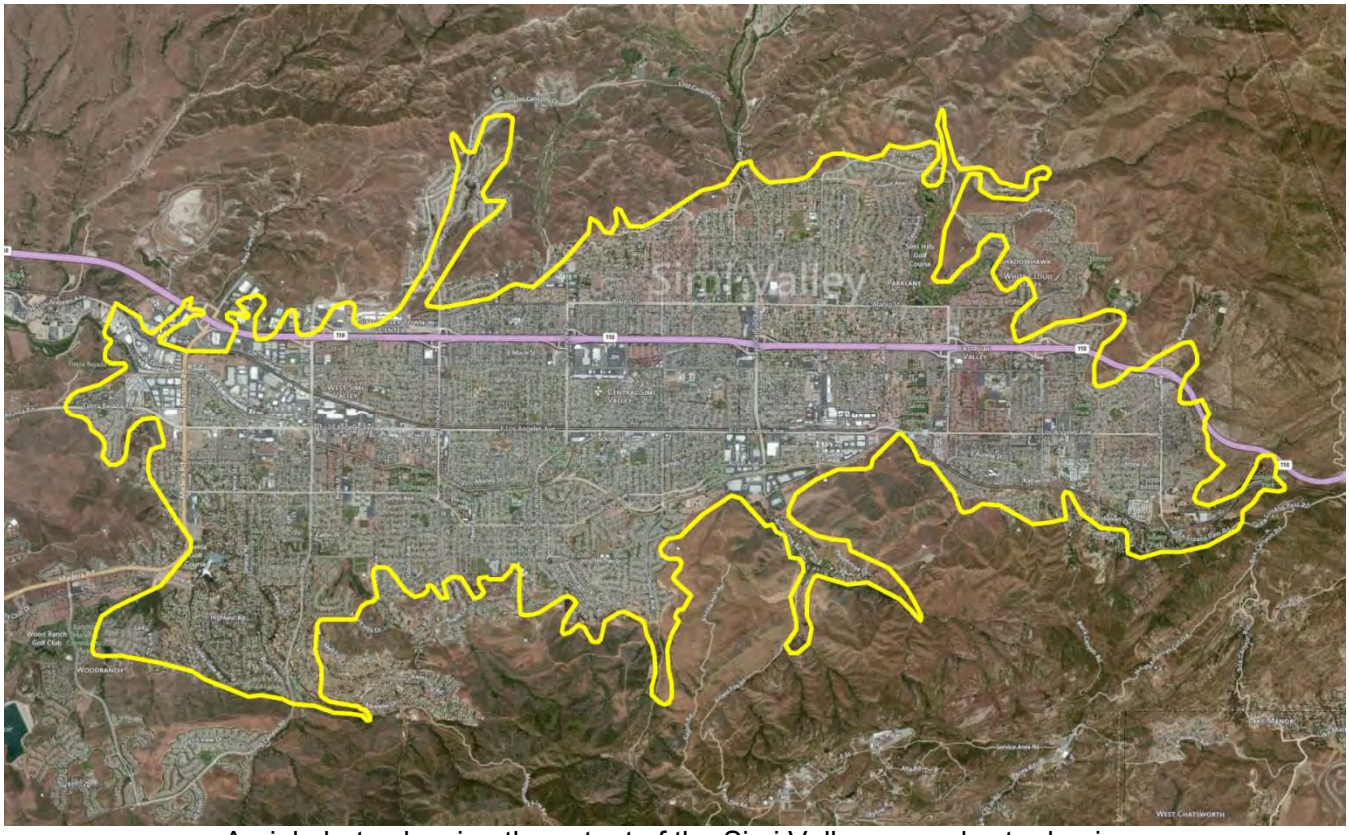
3.2.13 - Simi Valley Basin

The Simi Valley Basin drains to the west and, historically, water quality becomes more enriched in salts farther west in the basin. There are approximately 191 water supply wells in the Simi Valley Basin; 43 are active wells. Depth to water bearing material is approximately 5 to 25 feet below ground surface. The City of Simi Valley has a high water table at the west end of the valley and several extraction wells have been installed to pump down the water table when groundwater gets too high. Figure E-28, piper diagram, shows low variability in water quality of the wells sampled this year. There is no dominant cation but all three samples plot close to the calcium cation type; sulfate (SO_4^{2-}) is the dominant anion. The water is calcium sulfate type. The three wells sampled this year, all dewatering wells, located in the western half of the basin, have sulfate (SO_4^{2-}), and TDS concentrations above the secondary MCL for drinking water and one well has manganese (Mn^{+}) above the MCL and one has iron concentration that is about ten times the secondary MCL for drinking water. All three samples also have concentrations of boron and two have chloride that exceed agricultural beneficial uses, but neither constituent is above the primary MCL for drinking water. A water sample from one well was analyzed for Title 22 metals. None of the Title 22 metals was above the primary MCL for drinking water. Figure 3-22 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^{+}), potassium (K^{+}), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^{-}), bicarbonate (HCO_3^{-}), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the Simi Valley basin.



Aerial photo showing the extent of the Simi Valley groundwater basin.

SIMI VALLEY BASIN

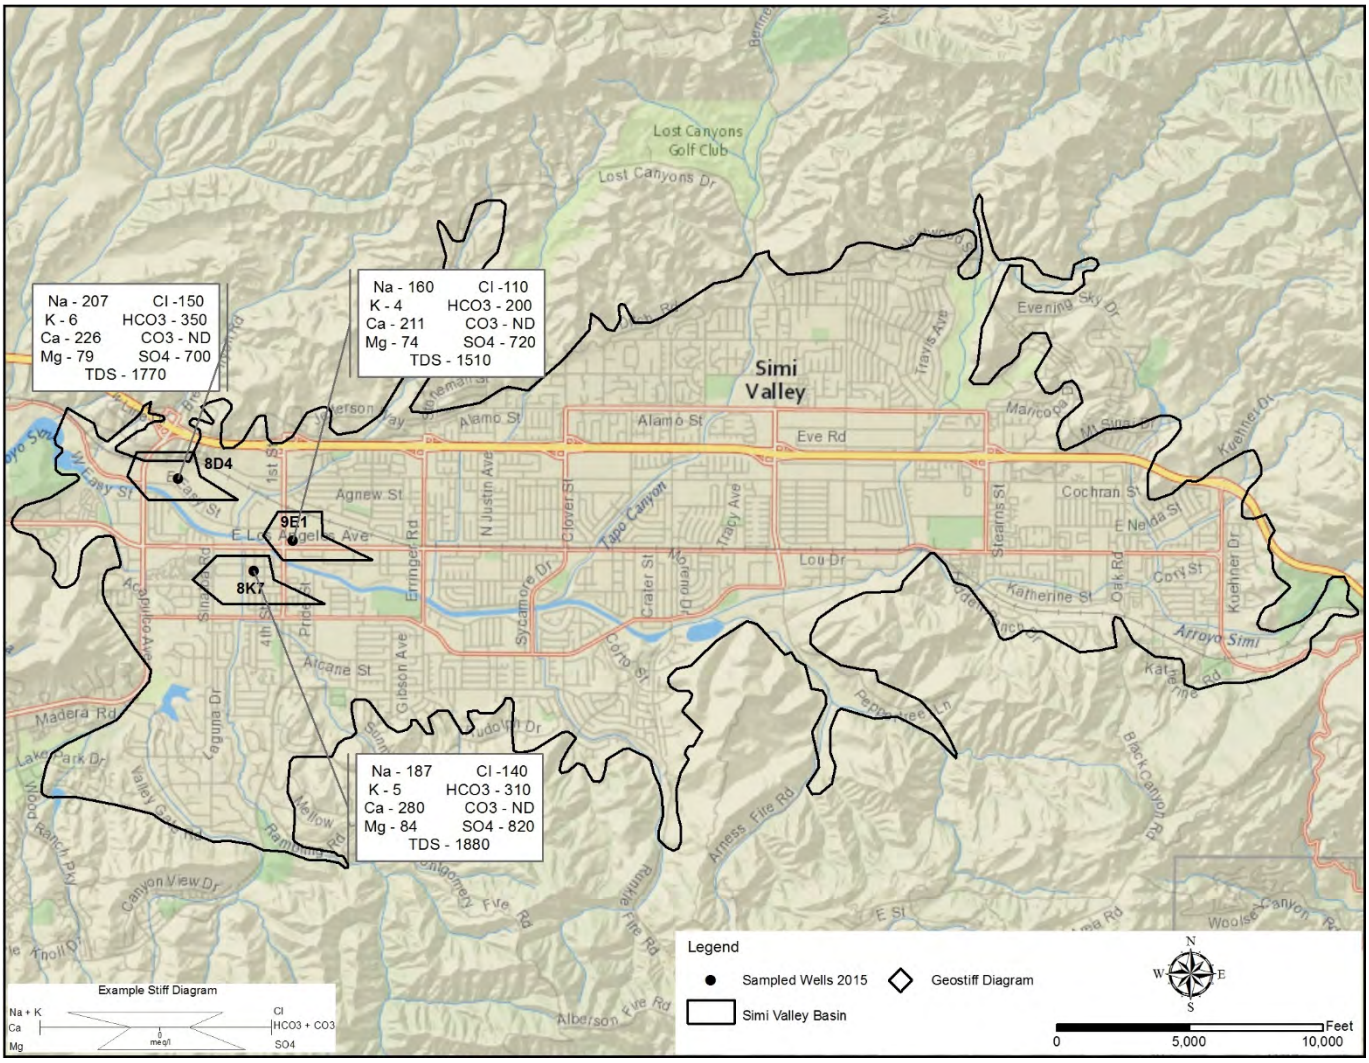


Figure 3-22: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagram.

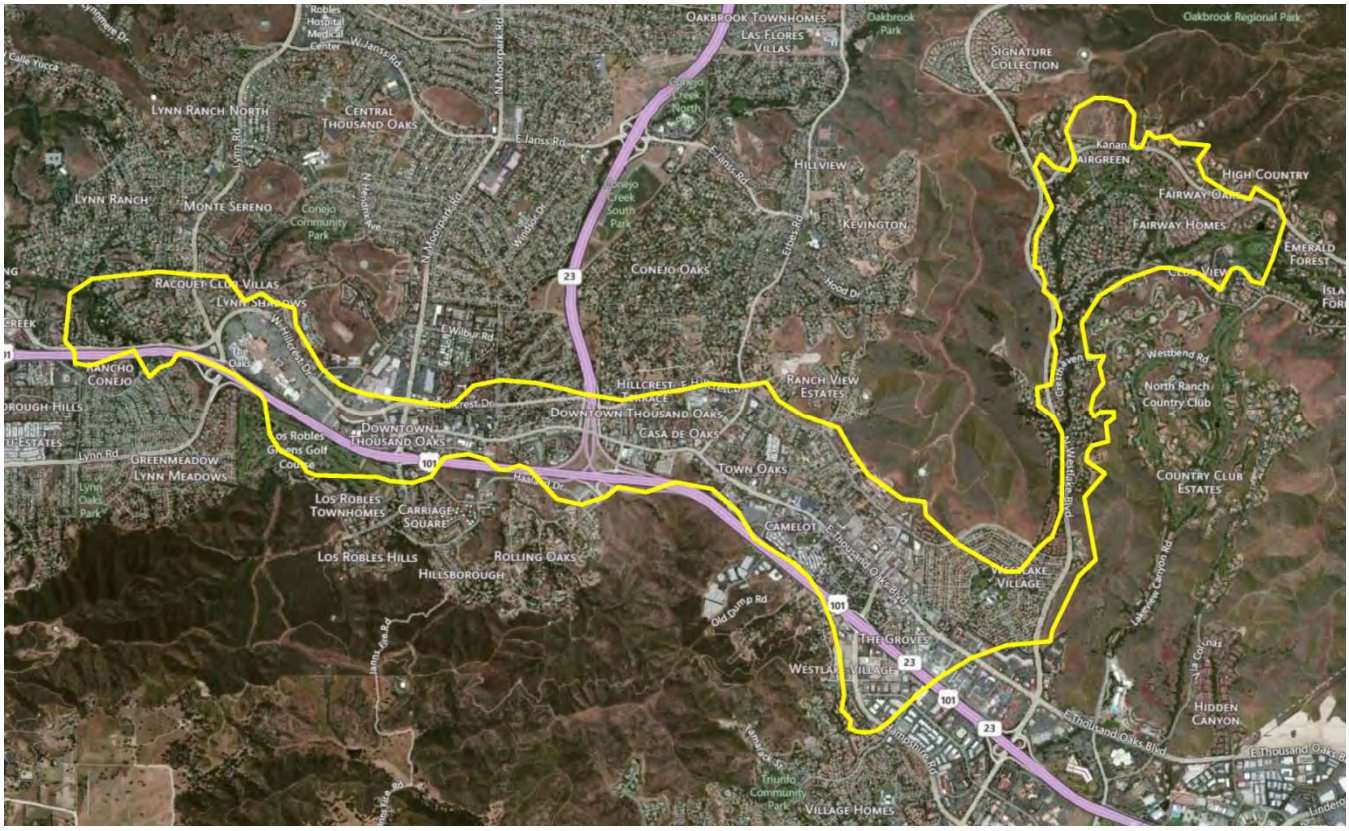
3.2.14 - Thousand Oaks Basin

The Thousand Oaks Basin has very few active water wells available for sampling. The depth to the water bearing unit is approximately 25 to 30 feet. There are approximately 194 water supply wells in the Thousand Oaks Basin; 18 are active wells. Two wells at the west end of the basin were sampled this year. Figure E-29, piper diagram, shows the water quality of the wells sampled this year. There is no dominant cation but the water plots close to the magnesium type (Mg^{2+}); sulfate (SO_4^{2-}) is the dominant anion in one sample and there is no dominant cation for the other well. The water is magnesium sulfate type. Concentrations of iron, sulfate (SO_4^{2-}) and TDS are above the secondary MCL for drinking water and manganese (Mn^{+}) is above the MCL in one sample. Neither sample was analyzed for Title 22 metals. Figure 3-23 shows approximate well location and concentrations of total dissolved solids (TDS), sodium (Na^{+}), potassium (K^{+}), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^{-}), bicarbonate (HCO_3^{-}), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in Thousand Oaks basin.



Aerial photo showing the extent of the Thousand Oaks groundwater basin.

THOUSAND OAKS BASIN

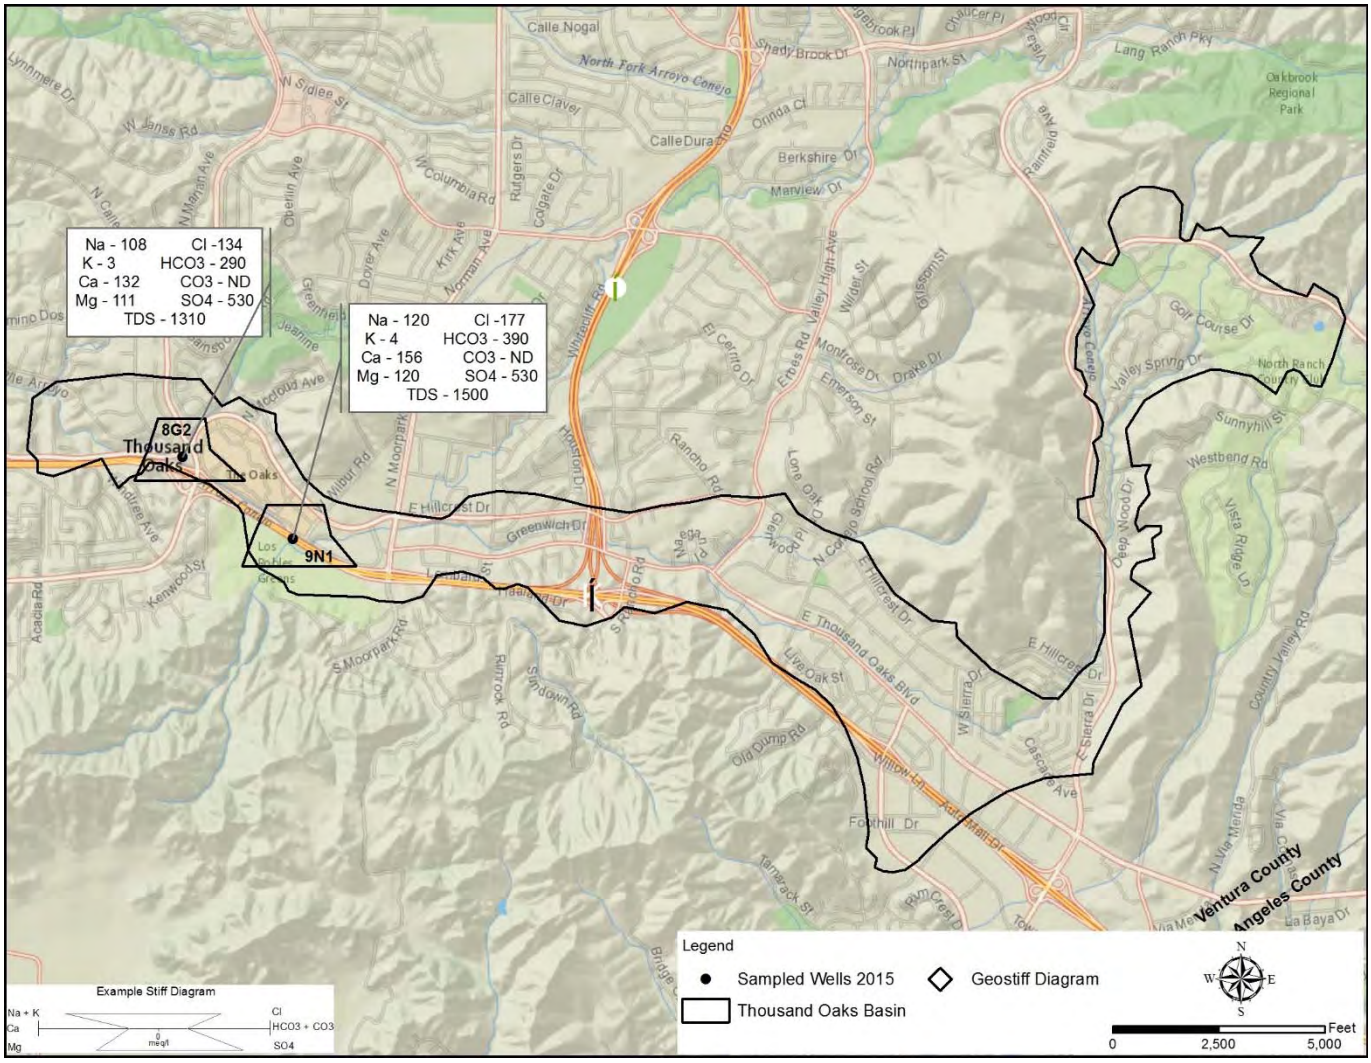


Figure 3-23: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagram.

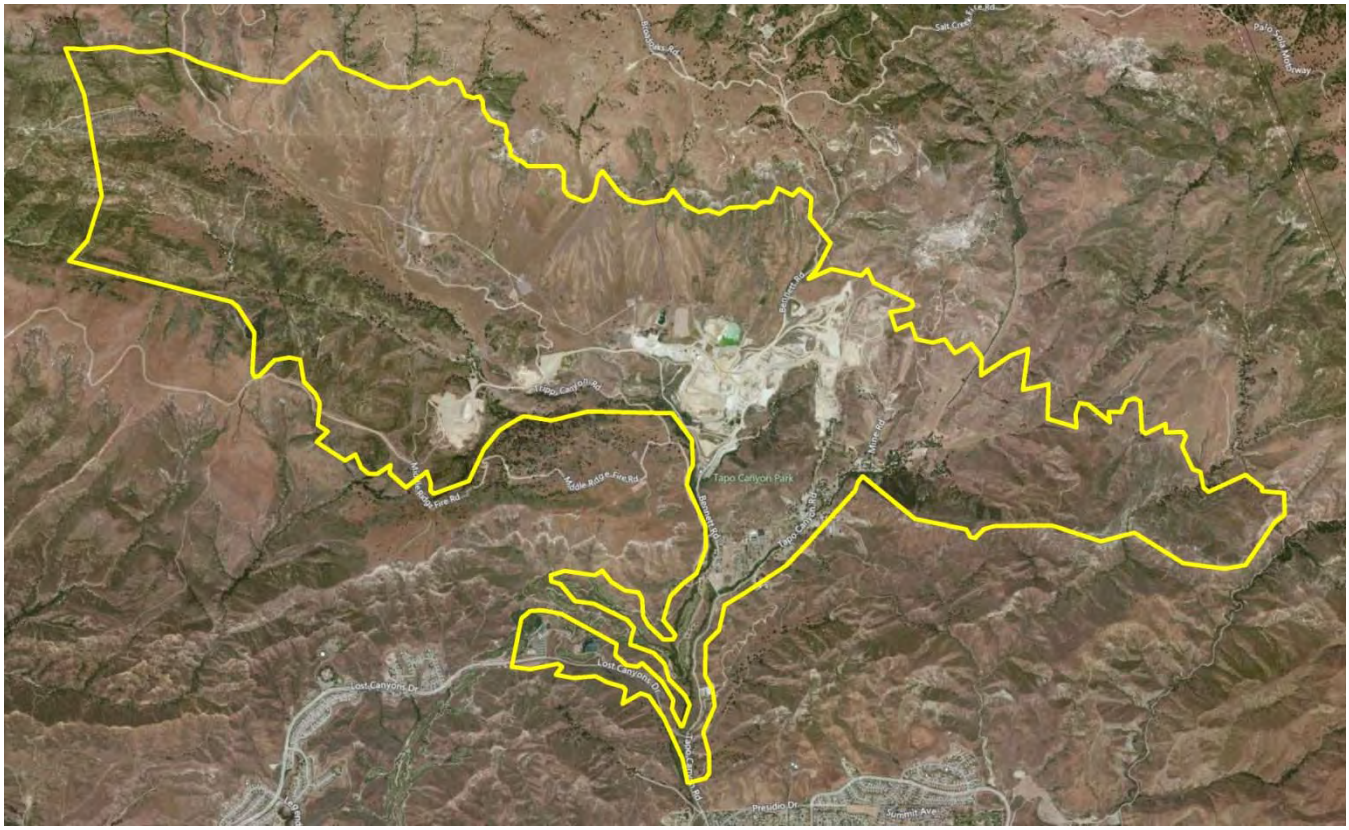
3.2.15 - Tapo/Gillibrand Basin

The Tapo/Gillibrand Basin is located to the north of Simi Valley. There are approximately 46 water supply wells in the Tapo/Gillibrand Basin; 42 are active wells. The City of Simi Valley operates several wells in the basin as a backup water supply. Two wells were sampled this year. Figure E-30, piper diagram, shows water quality of the wells sampled this year. Calcium is the dominant cation in both wells and sulfate (SO_4^{2-}) is the dominant anion in one of the wells sampled. The water is calcium sulfate type. TDS and SO_4^{2-} concentrations are above the secondary MCL for drinking water in both wells; iron (Fe) and manganese (Mn) are above the secondary MCL in one well. Neither well was analyzed for Title 22 metals. Figure 3-24 shows approximate well location and concentration of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the well sampled in Tapo/Gillibrand basin.



Aerial photo showing the extent of the Tapo/Gillibrand groundwater basin.

TAPO/GILLIBRAND BASIN

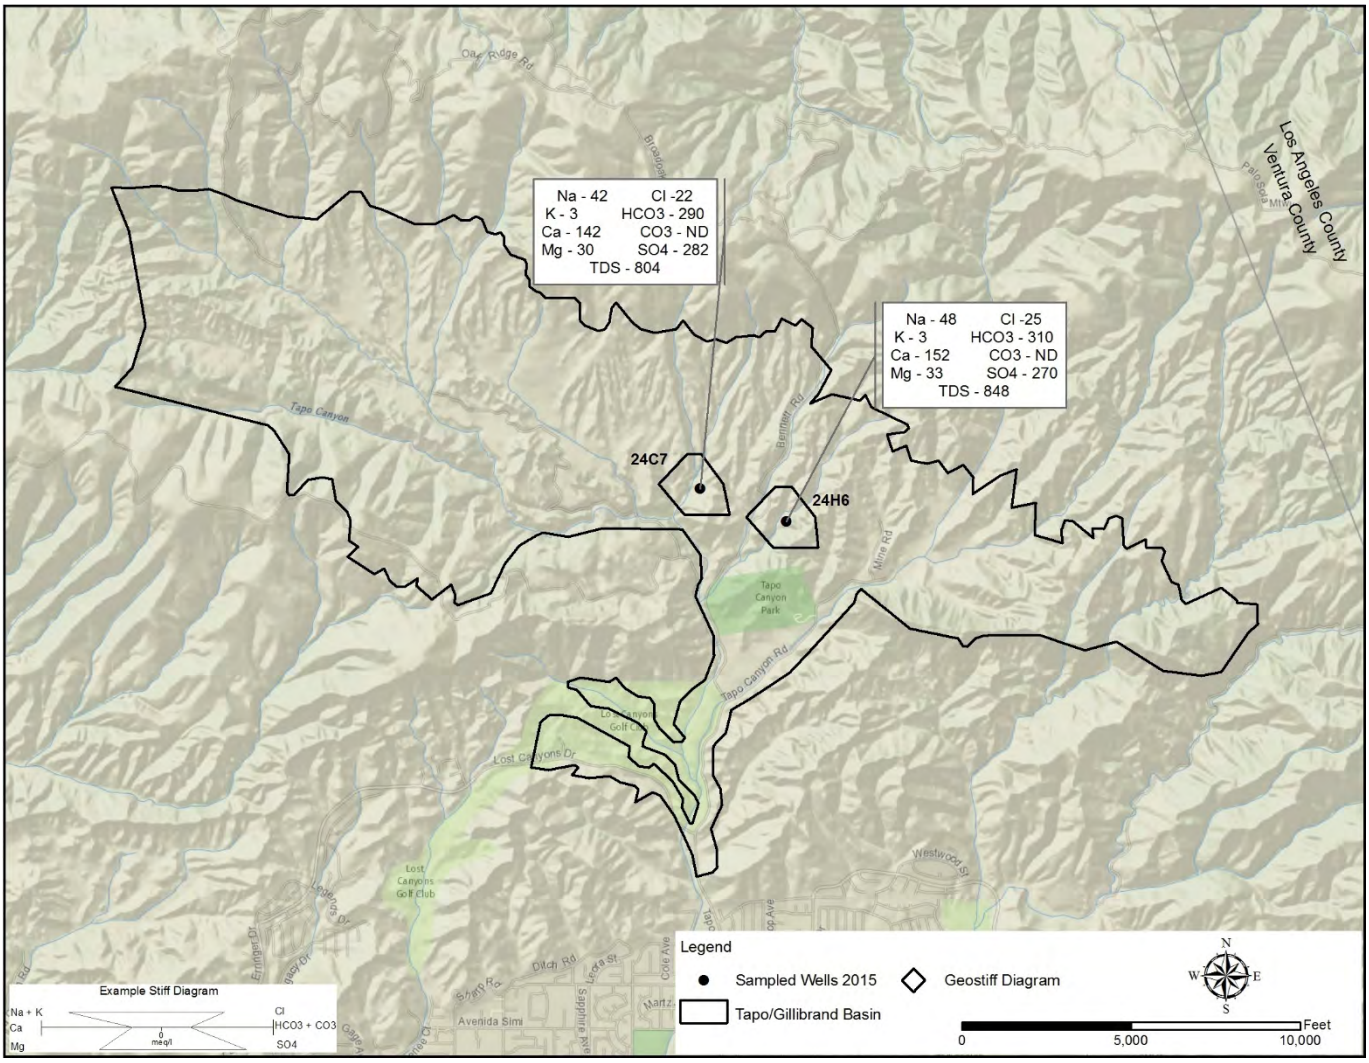


Figure 3-24: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagram.

3.2.16 - Arroyo Santa Rosa Basin

The water bearing units of the Arroyo Santa Rosa Basin occupy almost the entire area beneath the Santa Rosa Valley, but the area west of the Bailey Fault is generally considered to be hydrogeologically separate from the area east of the fault (1997 Santa Rosa Basin Groundwater Management Plan) although some leakage across the fault does occur (CMWD, 2013). Depth to water bearing material is approximately 50 feet. The water bearing units west of the fault are confined and those located east of the fault are unconfined. The degree of groundwater movement across the fault is not clearly understood. The Arroyo Santa Rosa Basin has a large area dedicated to agricultural use and a high number of individual septic systems; two main sources of nitrate to the groundwater. A large portion of recharge to the basin is discharge from the Thousand Oaks Hill Canyon Wastewater Treatment Plant. There are approximately 87 water supply wells in the Arroyo Santa Rosa Basin; 40 are active wells. Figure E-32, piper diagram, shows moderate variation in water quality of the wells sampled this year. Magnesium (Mg^{2+}) is the dominant cation in one sample and the remainder of the samples plot close to the magnesium cation type. Bicarbonate is the dominant anion for one of the samples; there is no dominant anion for the remainder. One of the water samples is magnesium bicarbonate type and the remainder are magnesium sulfate type. Water from seven of the nine wells sampled this year have nitrate (NO_3^-) concentrations higher than the primary MCL for drinking water. All nine wells have TDS concentrations above the secondary MCL; ranging from 775 to 1120 mg/l. Chloride (Cl^-) concentrations in eight of the wells are above the level that can cause agricultural beneficial uses for sensitive plants to be impaired, but are not above the primary MCL for drinking water. Two water samples were analyzed for Title 22 metals. Lead (Pb) was above the primary MCL for drinking water in one sample. None of the other Title 22 metals was above the primary MCL for drinking water. Figure E-34, piper diagram, shows a comparison of water chemistry between Tierra Rejada Basin and Arroyo Santa Rosa Basin groundwater. The water chemistry is similar but with more variation in the Tierra Rejada Samples. Figure 3-25 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the Arroyo Santa Rosa basin.

Aerial photo showing the extent of the Arroyo Santa Rosa groundwater basin.

ARROYO SANTA ROSA BASIN

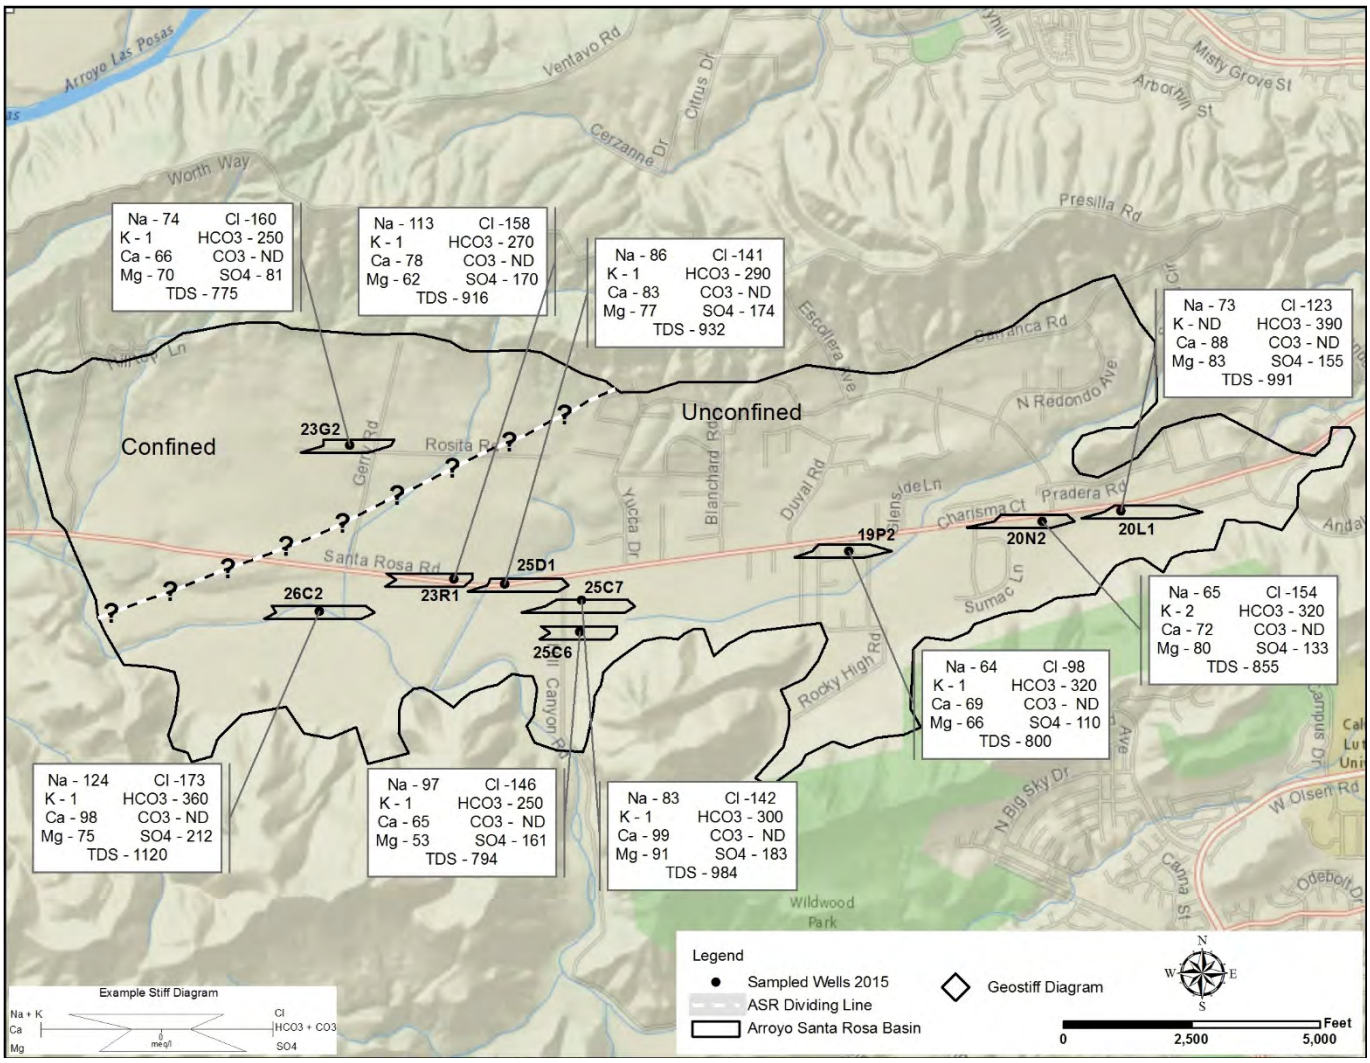

Figure 3-25: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams.

Figure 3-26 shows the geographic distribution of the wells sampled, with graduated symbols representing nitrate concentration for 2015. Figure 3-27 shows nitrate results for 2006 through 2015 in the same manner. The Groundwater Section has used three or more wells with nitrate concentrations above the state primary MCL in a given year as the criteria to classify the basin as nitrate-impacted. Comparison of the two shows that the Arroyo Santa Rosa Basin has remained nitrate impacted for many years. Management practices now in place include limiting the number of large animals and generally restricting septic systems to lots greater than 2.875 acres. It is not clear that the management practices are having the desired effect of reducing nitrate but no groundwater samples collected this year had nitrate (NO_3^-) concentration above 108 mg/l and in previous years some wells have been as high as 292 mg/l.

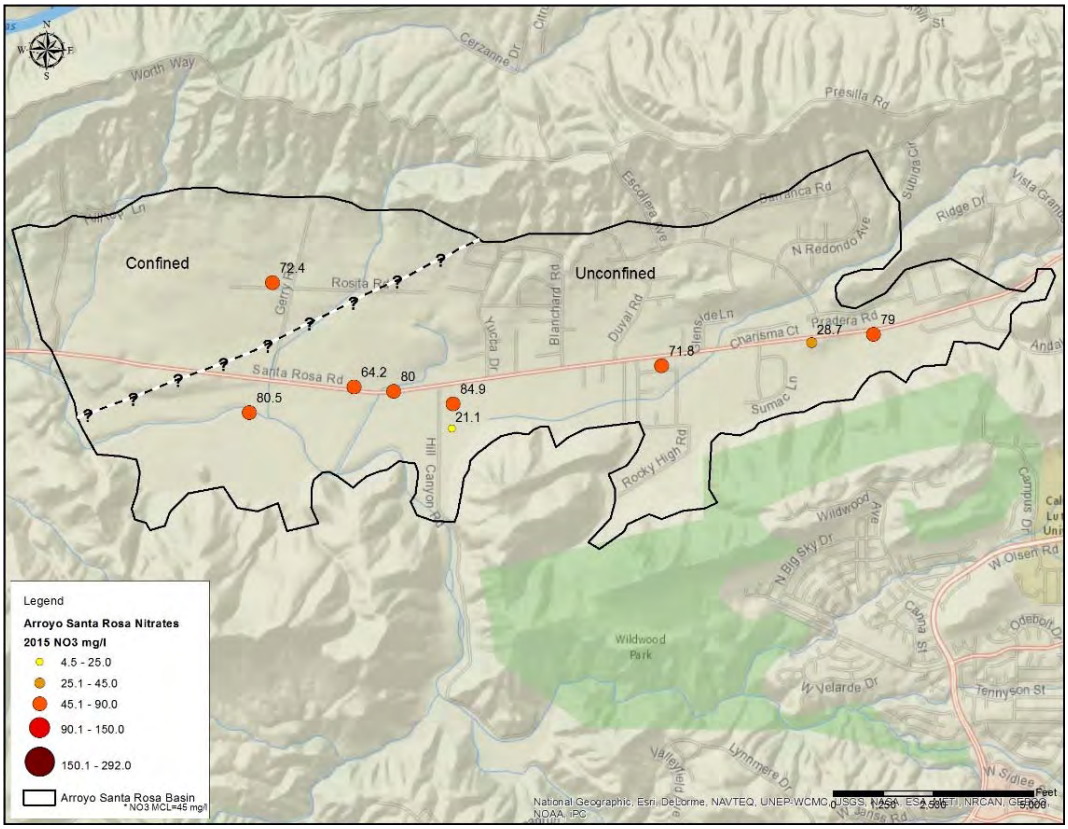

Figure 3-26: Map showing Nitrate results in mg/l for the year 2015.

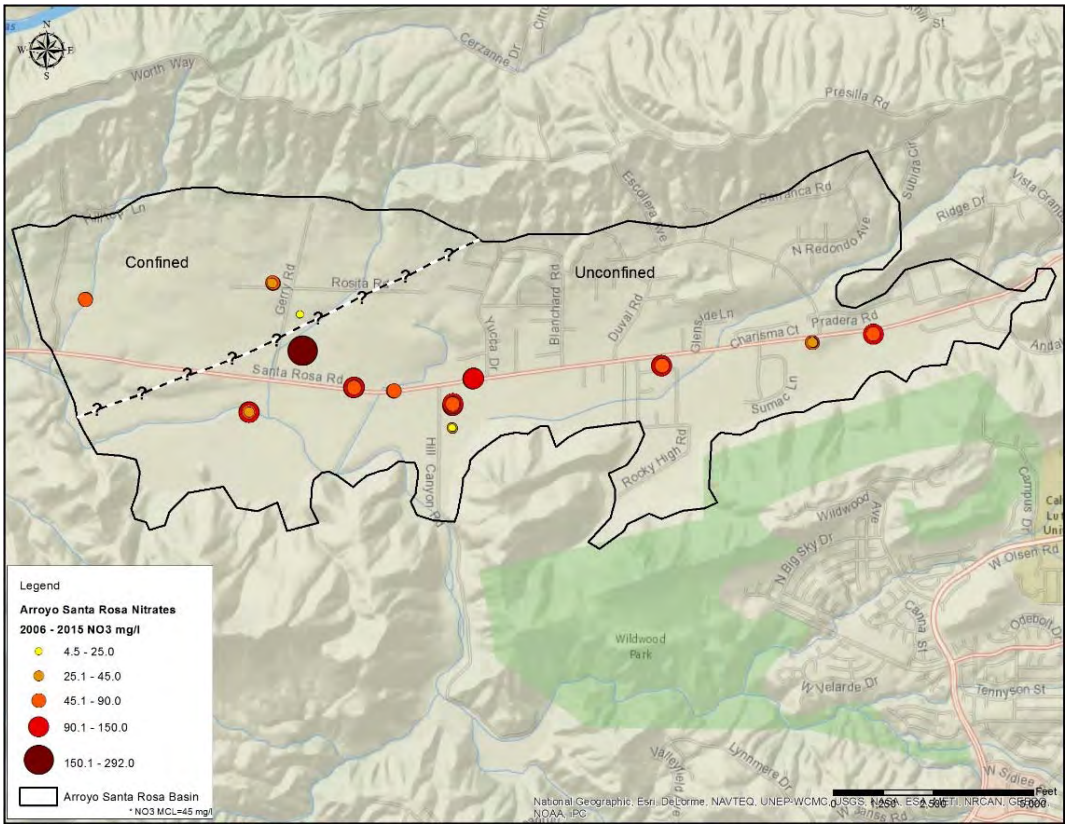

Figure 3-27: Map showing nitrate results for 2006 to 2015.

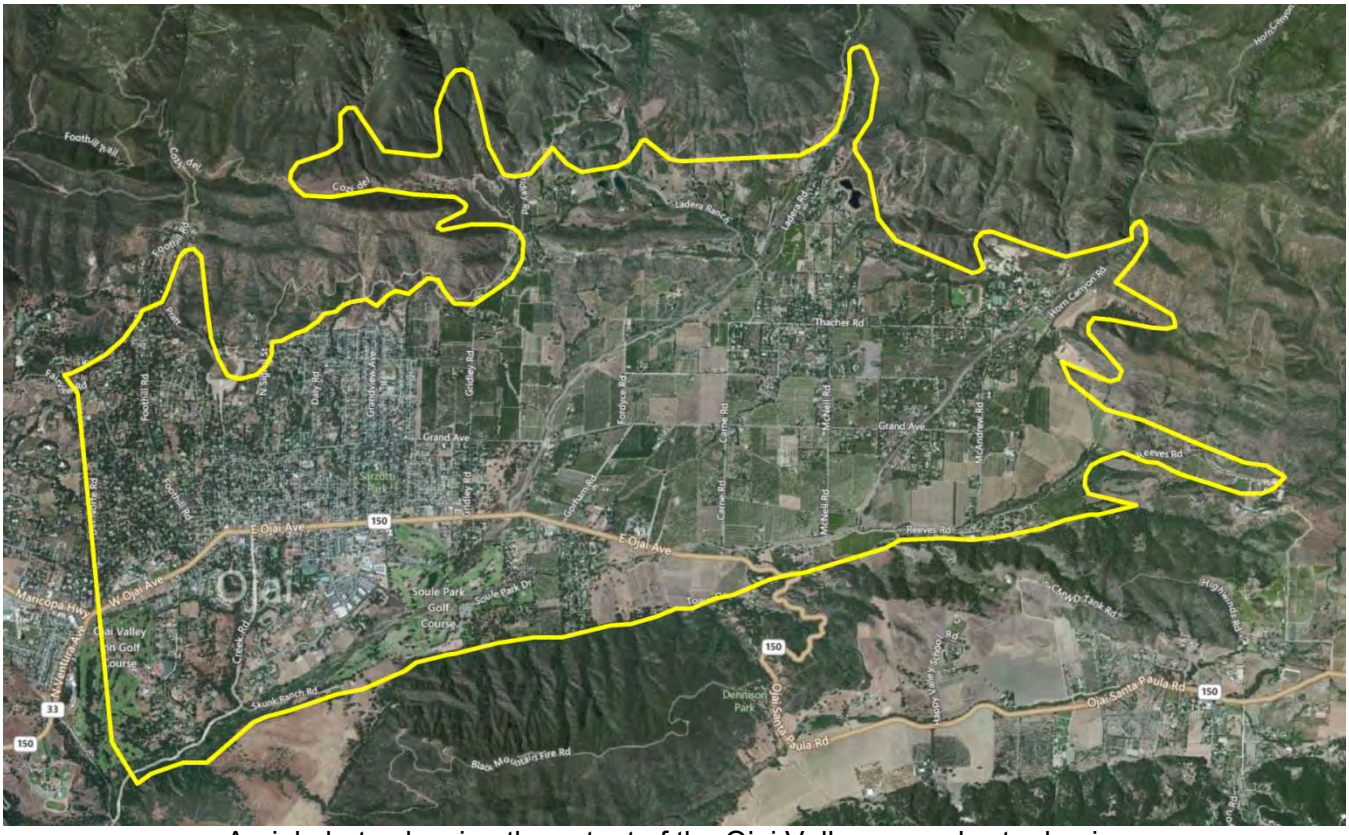
3.2.17 - Ojai Valley Basin

The aquifer system of the Ojai Valley Basin is considered unconfined except in the western end of the basin where a semi-confining to confining clay layer is present. The Ojai Valley Basin water quality is considered good. There are approximately 341 water supply wells in the Ojai Valley Basin; 191 are active wells. Depth to water bearing material is generally between 25 to 30 feet below ground surface. Figure E-36, piper diagram, shows high variation in water quality of the wells sampled this year. Calcium is the dominant cation group for eleven of the samples; sodium is the dominant cation group for one sample and the remaining three samples have no dominant cation. Sulfate (SO_4^{2-}) is the dominant anion for four samples; bicarbonate is the dominant anion for five of the samples, chloride (Cl^-) is the dominant anion for one sample and there is no dominant anion for the remaining five samples but they plot close to the bicarbonate anion type. Four samples are calcium bicarbonate type; one sample is sodium bicarbonate type; the remaining samples are calcium sulfate type.

Fourteen of the fifteen wells sampled have TDS concentrations above the secondary MCL for drinking water. TDS ranges from 421 to 1520 mg/l. Two wells have iron (Fe), four wells have manganese (Mn), one well has sulfate (SO_4^{2-}), one has chloride (Cl^-) and one has nitrate (NO_3^{2-}) concentrations above the secondary MCL for drinking water. Water samples from three wells were analyzed for Title 22 metals. One well has lead (Pb) above the primary MCL for drinking water. None of the remaining Title 22 metals were above the primary MCL for drinking water. Figure 3-28 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the Ojai Valley basin.



Aerial photo showing the extent of the Ojai Valley groundwater basin.

OJAI VALLEY BASIN

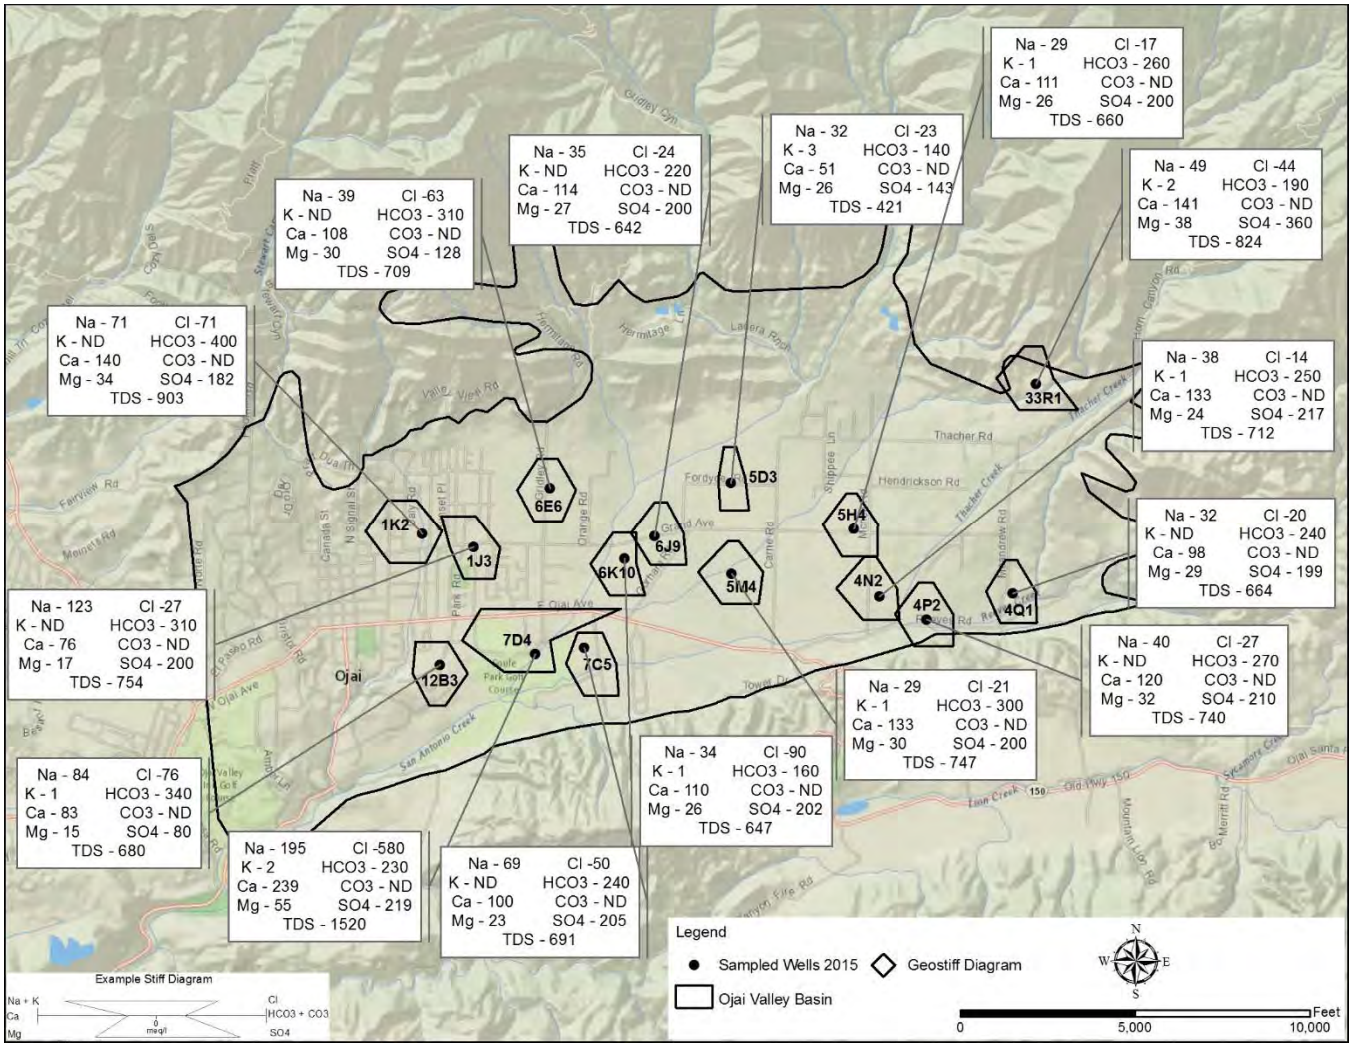


Figure 3-28: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams.

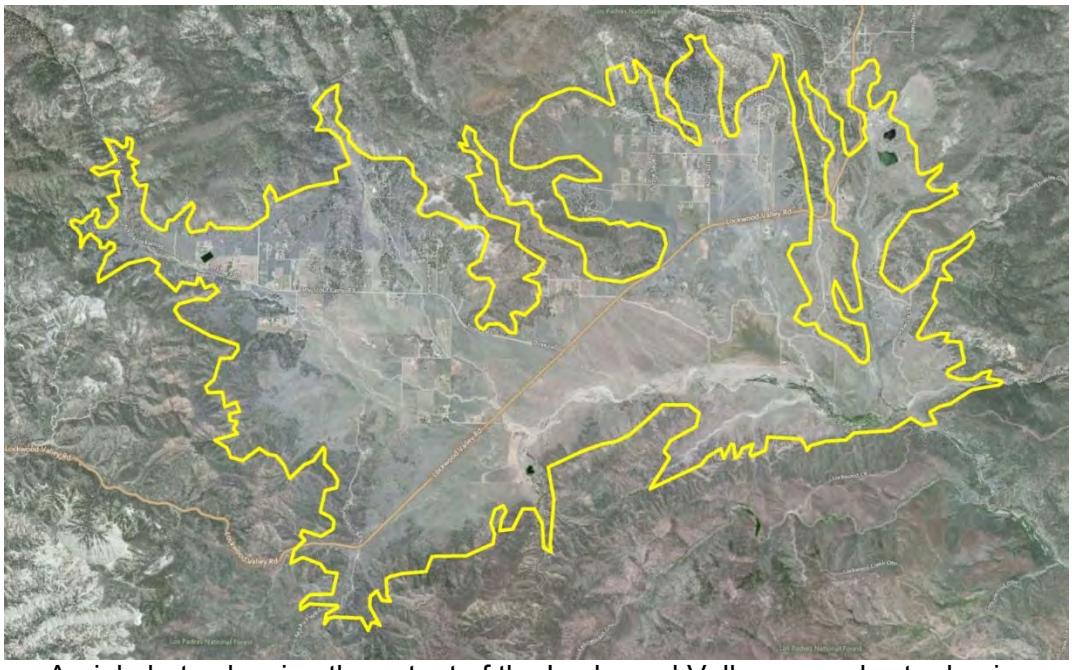
3.2.18 - Lockwood Valley Basin

The Lockwood Valley Basin groundwater quality ranges from good to unhealthful. The basin covers a large geographic area, approximately 34.1 square miles. Depth to water bearing material is approximately 55 to 60 feet. There are approximately 260 water supply wells in the Lockwood Valley Basin; 216 are active wells. Figure E-31, piper diagram, shows moderate variation in groundwater chemistry of the wells sampled this year. Calcium is the dominant cation and bicarbonate is the dominant anion. The two samples are calcium bicarbonate type. Two wells were sampled this year and both have TDS concentrations above the secondary MCL for drinking water and five have sulfate (SO_4^{2-}) above the secondary MCL. Samples from all six wells were also analyzed for Title 22 metals and radionuclides. One has arsenic above the California MCL for Title 22 metals, but four are above the EPA standards for drinking water. None of the remaining Title 22 metals were above the primary MCL for drinking water.

The result for gross alpha on five of the samples was above 5 pCi/L; that level requires the sample to be analyzed for uranium. In 2004, the Drinking Water Branch of the California Department of Public Health issued an Initial Monitoring and MCL Compliance Determination flow chart. The flow chart is used to determine the source of gross alpha for determining compliance in community water systems. Based on the flow chart, naturally occurring uranium was determined to be the source of the gross alpha in these samples. The geologic source(s) of the radionuclides have not been investigated. Following the additional uranium testing, radionuclides were determined to be above the MCL for drinking water in only one of the samples. Figure 3-29 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the Lockwood Valley basin.



Aerial photo showing the extent of the Lockwood Valley groundwater basin.

LOCKWOOD VALLEY BASIN

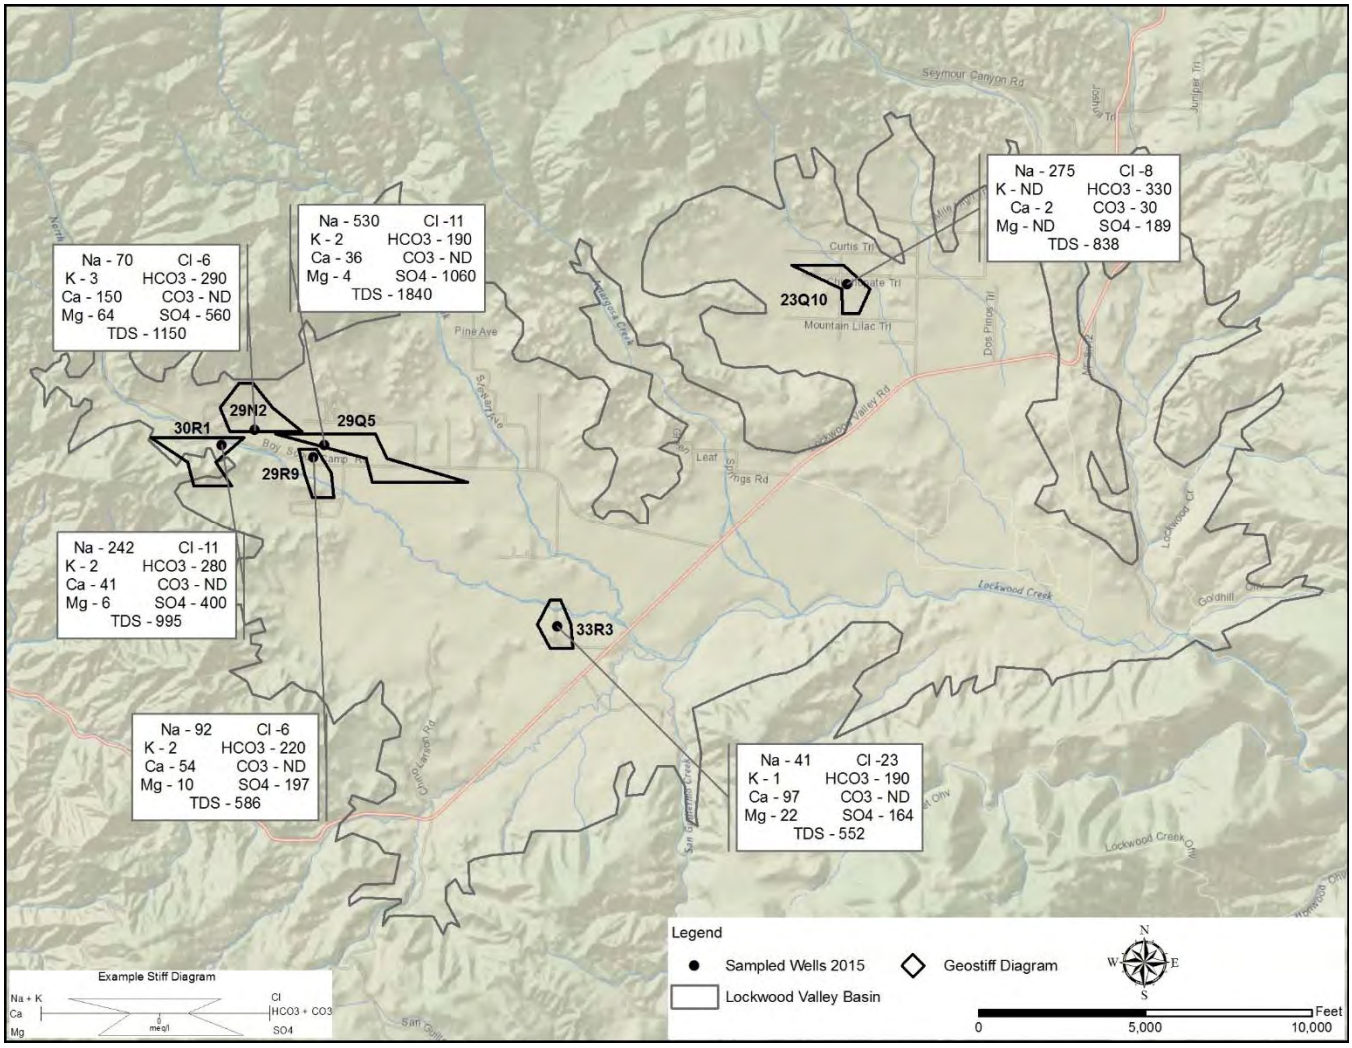


Figure 3-29: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagram.

3.2.19 - Tierra Rejada Valley Basin

Depth to water bearing materials varies between 20 to 80 feet. There are approximately 51 water supply wells in the Tierra Rejada Valley Basin; 31 are active. Eight wells were sampled this year. Figure E-33, piper diagram, shows high variation in water quality. The dominant cation for two wells is magnesium (Mg^{2+}); the remainder have no dominant cation but plot close to the magnesium type. The dominant anion for two samples is bicarbonate; the remainder have no dominant anion. One well is calcium bicarbonate, type, one is magnesium bicarbonate type and the remaining six are calcium sulfate type. All eight wells have concentrations above the secondary MCL for TDS; ranging from 503 to 1000 mg/l. One well is above the MCL for iron, one above the MCL for manganese and nitrate was above the MCL for drinking water in two samples this year. Samples from two wells were also analyzed for Title 22 metals. No Title 22 metal was above the primary MCL for drinking water. Figure E-34, piper diagram, shows a comparison of water chemistry between Tierra Rejada and Arroyo Santa Rosa Basins.

Chemistry in the two basins is similar but there is more variation in Tierra Rejada with slightly higher bicarbonate and sulfate. Figure 3-30 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^{+}), potassium (K^{+}), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^{-}), bicarbonate (HCO_3^{-}), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the Tierra Rejada basin.

Aerial photo showing the extent of the Tierra Rejada Valley groundwater basin.

TIERRA REJADA BASIN

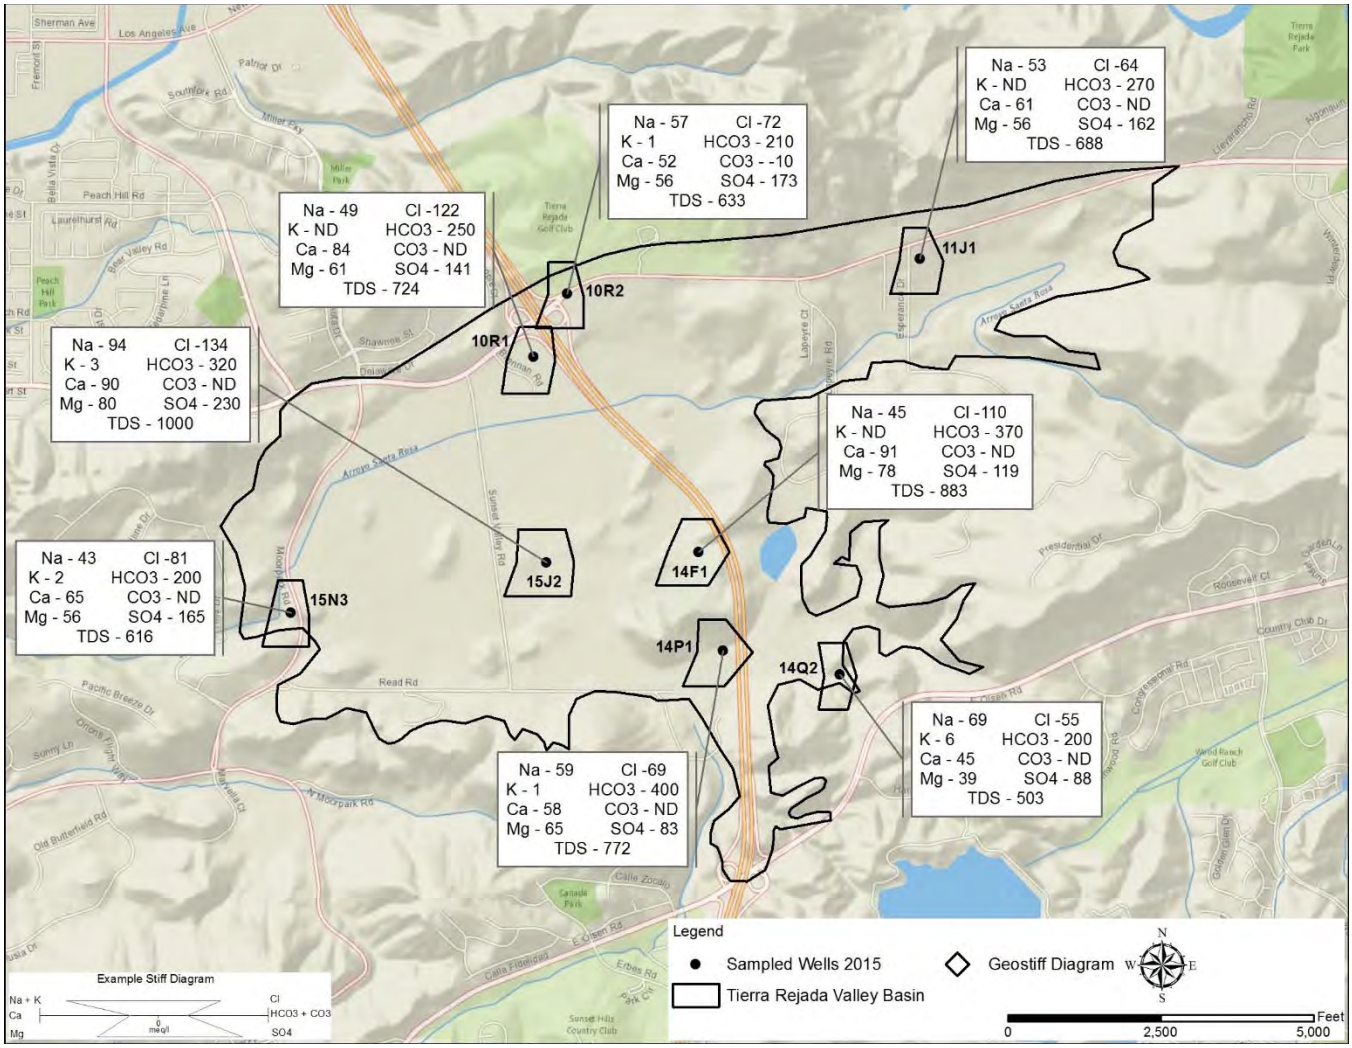

Figure 3-30: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams.

Figure 3-31 below shows nitrate concentrations for wells sampled in Tierra Rejada Basin in 2015. Groundwater from two of the wells sampled this year has a nitrate concentration that exceeds the primary MCL for drinking water. Other wells sampled in the past that had elevated nitrate concentrations were not available for sampling this year.

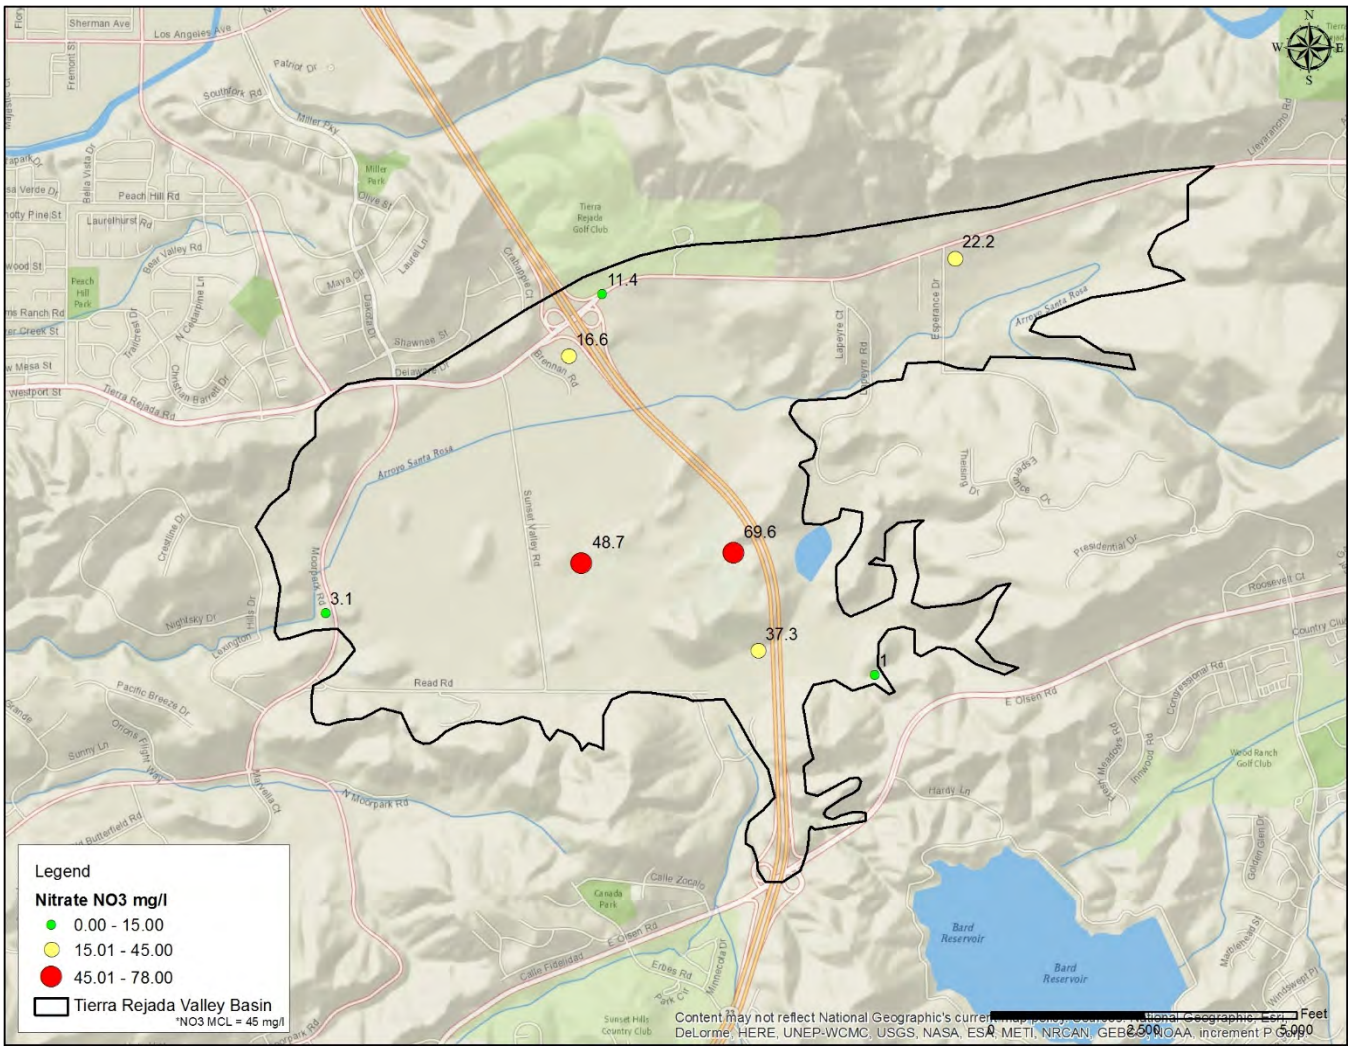

Figure 3-31: Map showing nitrate concentrations (mg/l). Two of the eight wells sampled this year have a nitrate concentration above the MCL for drinking water.

3.2.20 - Upper Ventura River Basin

The Upper Ventura River Basin is mainly composed of thin alluvial deposits. There are approximately 293 water supply wells in the Upper Ventura River Basin; 164 are active wells. Figure E-25, piper diagram, shows moderate variation in water quality. The dominant cation for one well is calcium and the dominant cation for one well is sodium type. There is no dominant anion for either well. One well is sodium sulfate type and one well is calcium sulfate type. Both samples have TDS concentrations that exceed the secondary MCL for drinking water; ranging from 548 to 815 mg/l. One well has manganese (Mn^{+}) above the secondary MCL for drinking water. A sample from one well was also analyzed for Title 22 metals. Lead (Pb) was above the primary MCL for drinking water but no other Title 22 metal was above the MCL. Figure E-26, piper diagram, shows a comparison of the water chemistry for the Upper and Lower Ventura River Basins. Water chemistry type is similar except the Upper Ventura River basin has a higher calcium concentration and lower sulfate. Figure 3-32 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^{+}), potassium (K^{+}), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^{-}), bicarbonate (HCO_3^{-}), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the Upper Ventura River basin.

Aerial photo showing the extent of the Upper Ventura River groundwater basin.

UPPER VENTURA RIVER BASIN

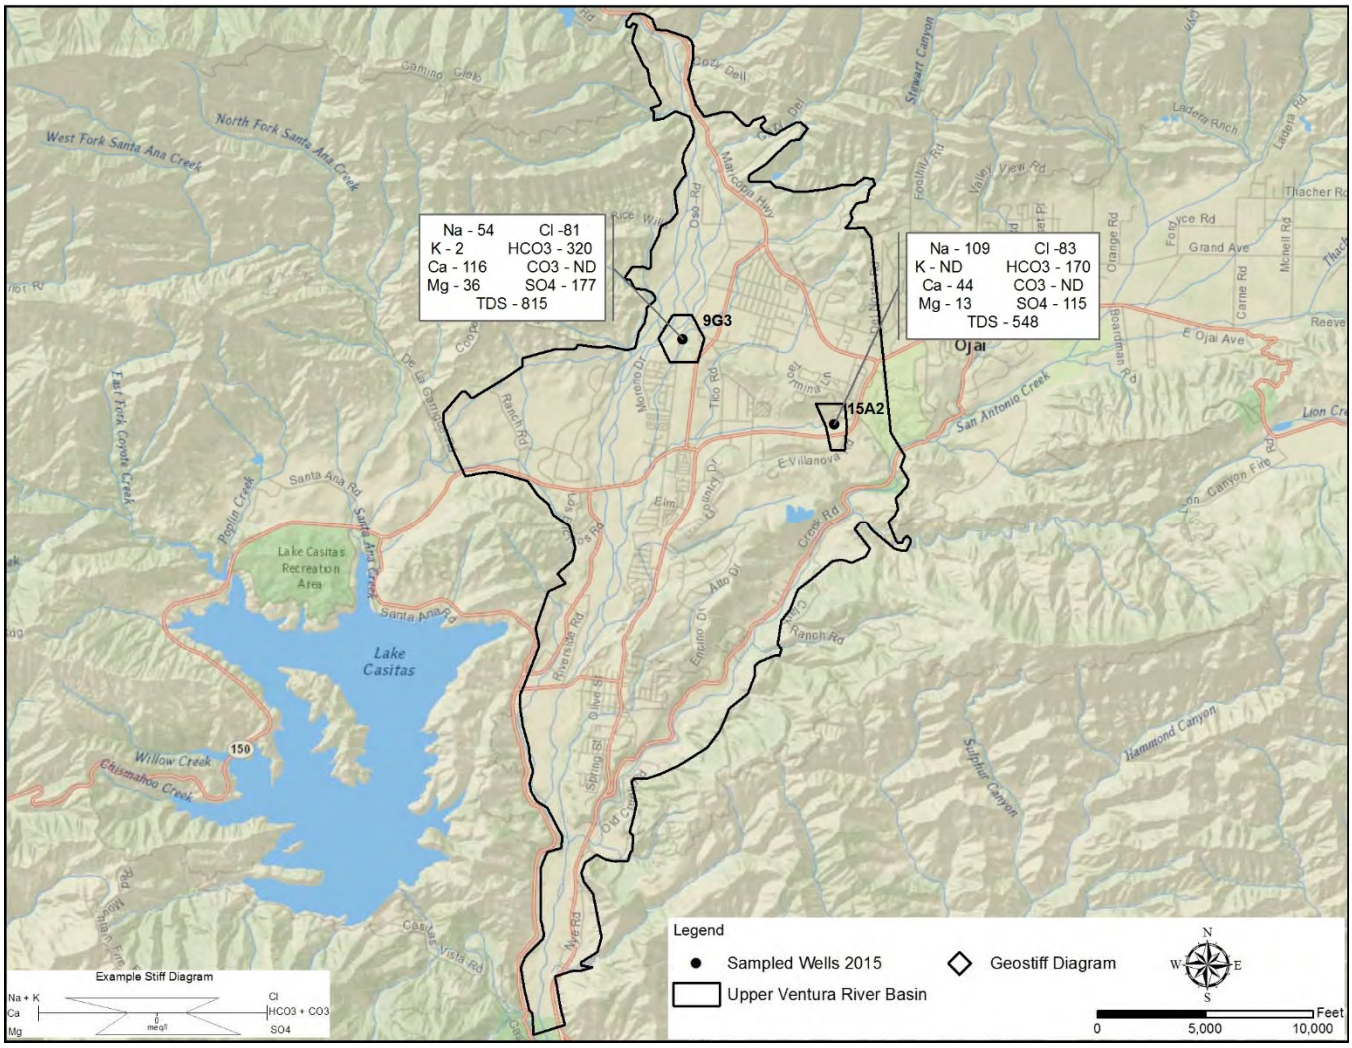

Figure 3-32: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams.

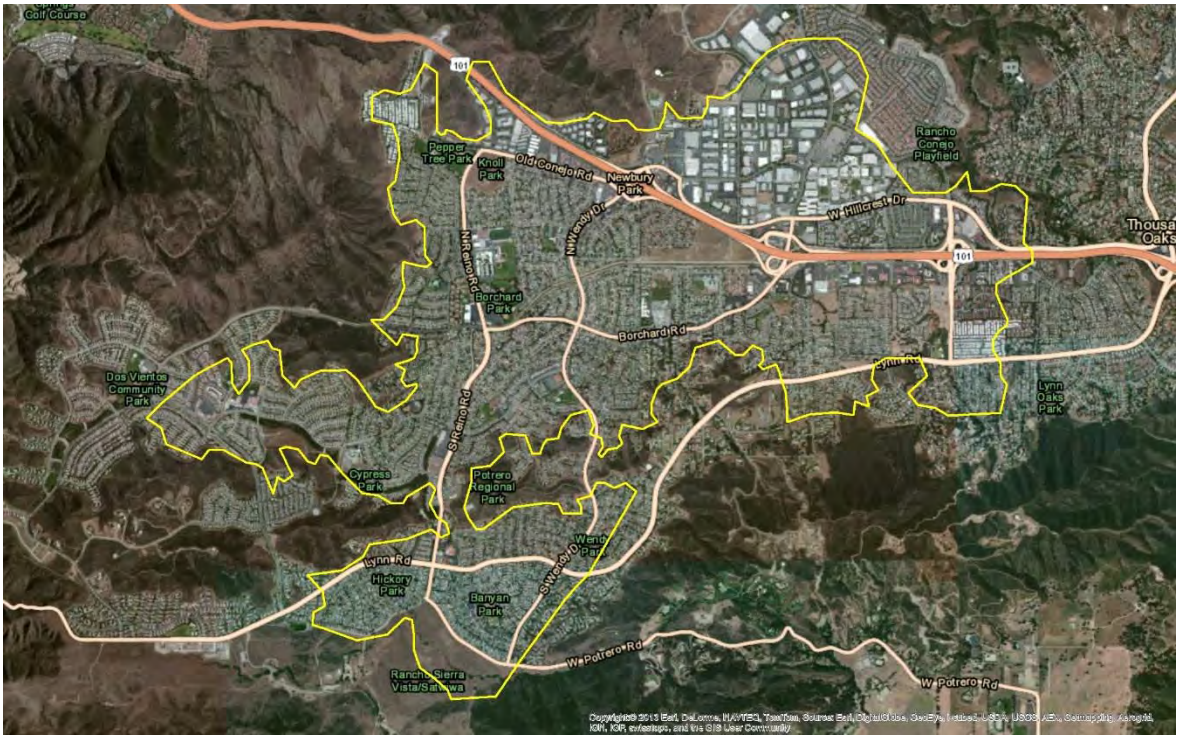
3.2.21 – Conejo Valley Basin

The Conejo Valley Basin has very few active water wells available for sampling. The depth to groundwater averages about 50 feet. There are approximately 167 wells in the Conejo Valley Basin; 11 are active water supply wells. One well located at the northwest corner of the basin was sampled this year. Figure E-38, piper diagram, shows water quality of the well sampled this year. Magnesium is the dominant cation; there is no dominant anion. The water is magnesium bicarbonate type. TDS concentration is above the secondary MCL for drinking water. The sample was analyzed for Title 22 metals. Lead was above the MCL but no other Title 22 metal was above the MCL for drinking water.

Figure 3-33 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the Upper Ventura River basin.



Aerial photo showing the extent of the Conejo Valley groundwater basin.

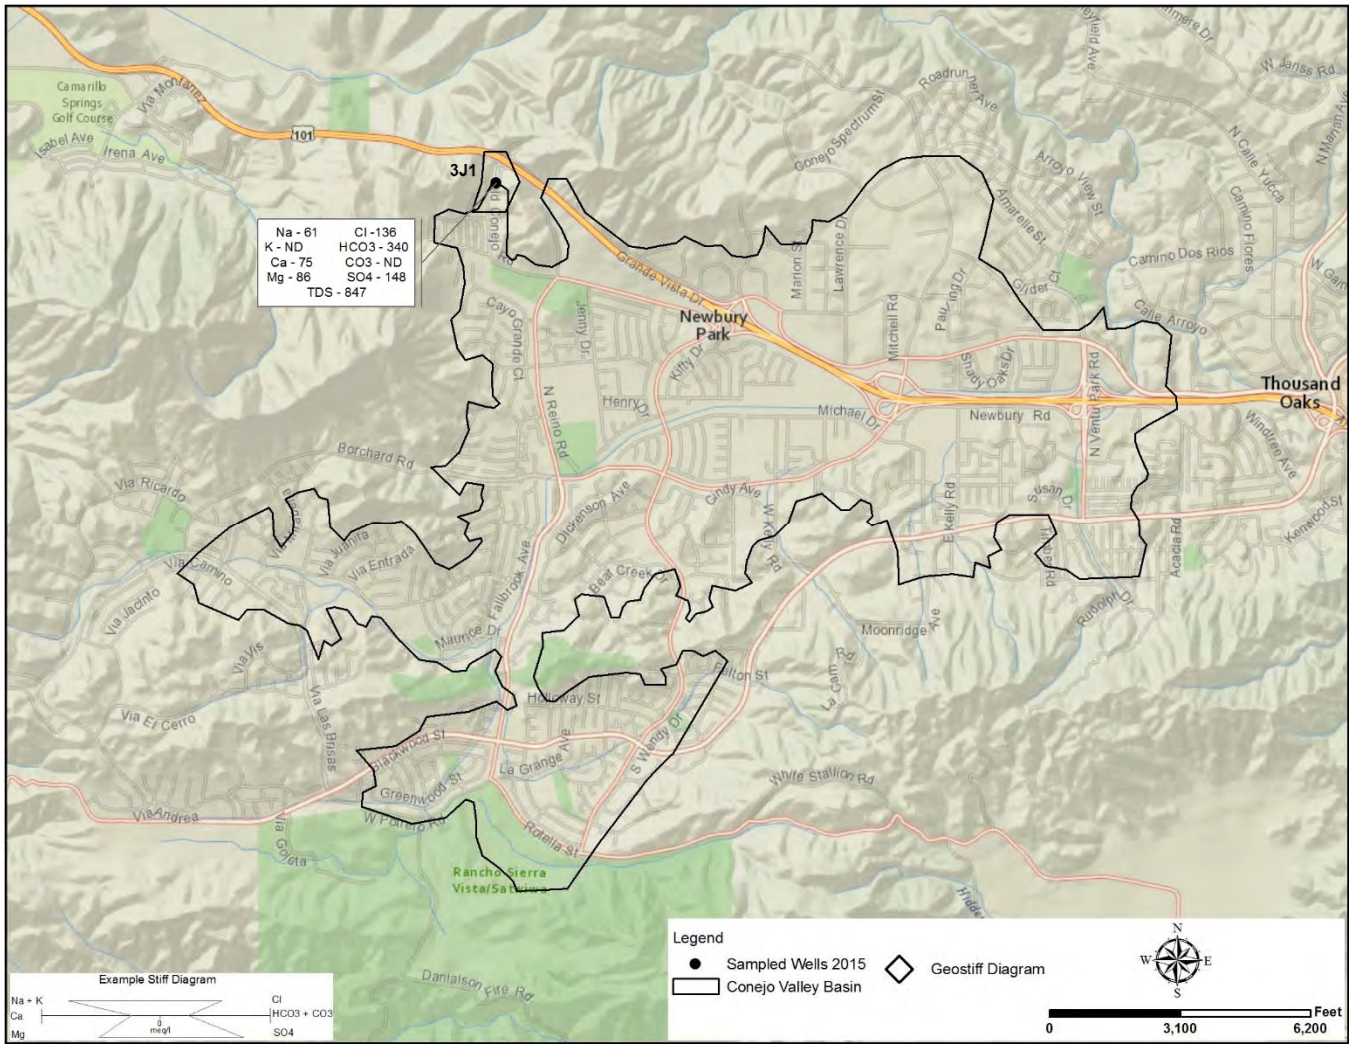


Figure 3-33: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagrams.

3.2.22 - North Coast Basin

The North Coast Basin does not fit the definition of a basin based solely on the Glossary of Geology definition that defines a basin as an aquifer or aquifer system having well defined boundaries and more or less definite areas of recharge and discharge. The North Coast Basin consists of narrow, thin strips of permeable sediments and marine terrace deposits along the coastline from Rincon Creek to just north west of the Ventura River. There are 26 water supply wells in the North Coast Basin; only 8 are active wells with the majority in the northwest portion along Rincon Creek. Water samples were collected from two wells at the northwest end of the basin. Figure E-39, piper diagram, shows moderate variation in the water quality of the wells sampled this year. There is no dominant cation and no dominant anion. The water in both wells is calcium sulfate type. Both samples have TDS above the secondary MCL, and one sample has sulfate (SO_4^{2-}) concentration above the secondary MCL. Figure 3-34 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^+), potassium (K^+), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^-), bicarbonate (HCO_3^-), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the North Coast basin.

Aerial photo showing the extent of the North Coast groundwater basin.

NORTH COAST BASIN

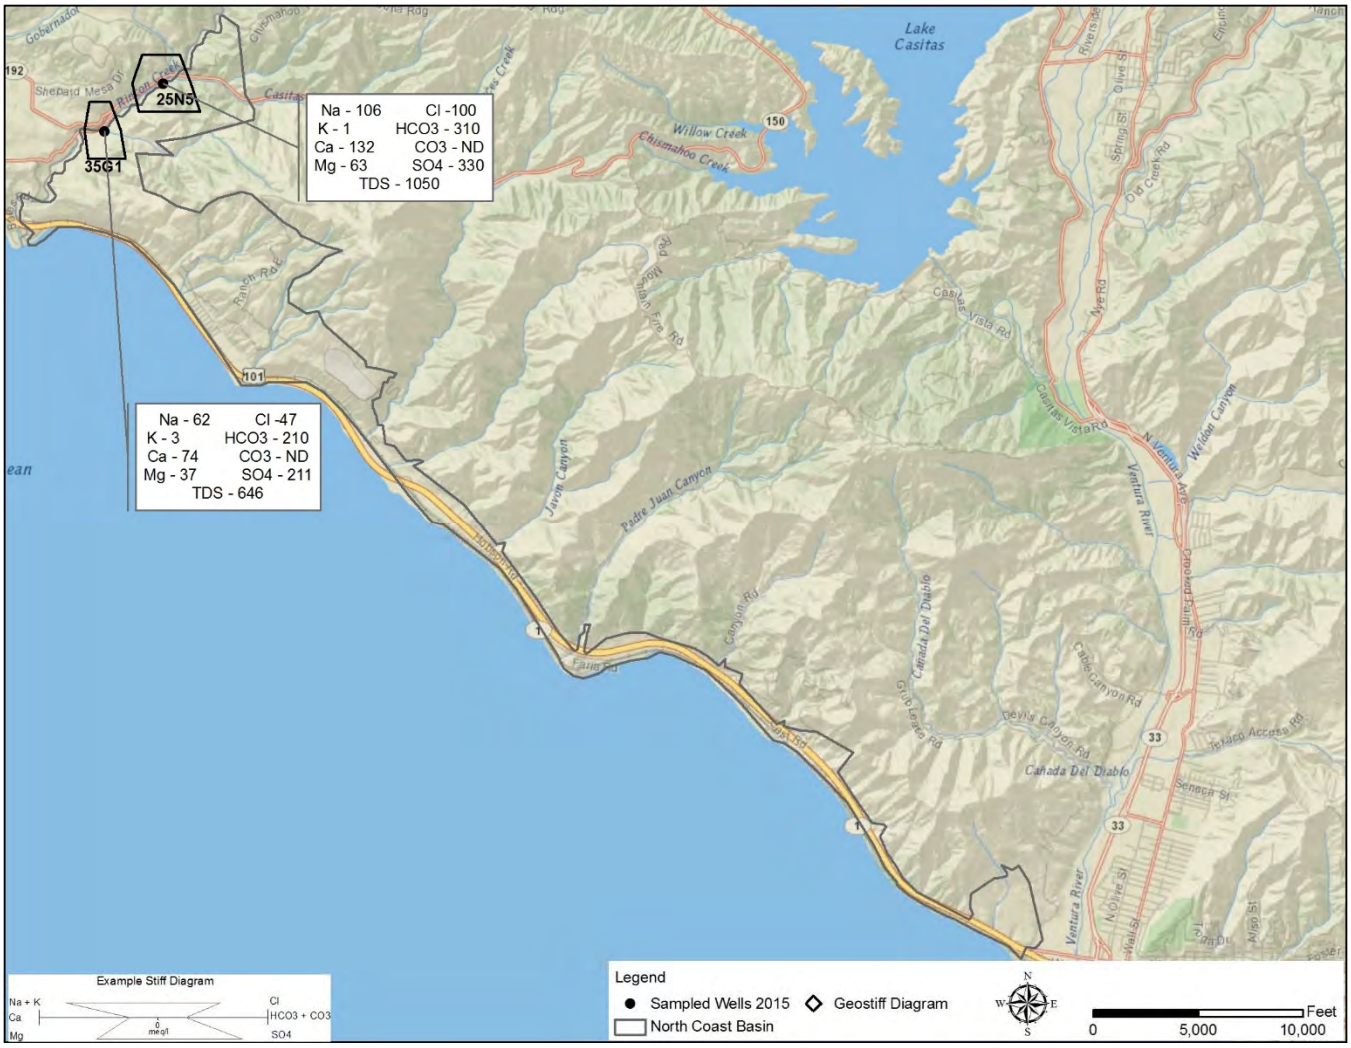

Figure 3-34: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents and piper diagram.

3.2.23 - Upper Ojai Basin

The Upper Ojai Basin is a small, linear valley southeast of and at a higher elevation than the Ojai Valley Basin. The average thickness of water bearing deposits is approximately 60 feet and is encountered approximately 45 to 60 feet below ground surface. Groundwater quality is considered good, but varies seasonally and usually has better quality during winter months. There are approximately 149 water supply wells in the Upper Ojai Basin; 106 are active wells. Three wells were sampled this year. Figure E-35, piper diagram, shows high variation in the water quality of the wells sampled this year. Calcium is the dominant cation in one sample and there is no dominant cation in the remaining two samples but they plot close to the calcium cation type. Bicarbonate is the dominant anion in two samples, and sulfate is the dominant anion in the remaining sample. The water is calcium sulfate type in one sample and calcium bicarbonate type in the other two samples. TDS for the wells sampled this year ranged from 341 to 595 mg/l and is above the secondary MCL for drinking water in one of the wells. One well has iron (Fe) above the MCL for drinking water and two have manganese (Mn^{+}) concentrations above the MCL for drinking water. No water sample was analyzed for Title 22 metals. Figure 3-35 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^{+}), potassium (K^{+}), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^{-}), bicarbonate (HCO_3^{-}), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled.

Aerial photo showing the extent of the Upper Ojai groundwater basin.

UPPER OJAI BASIN

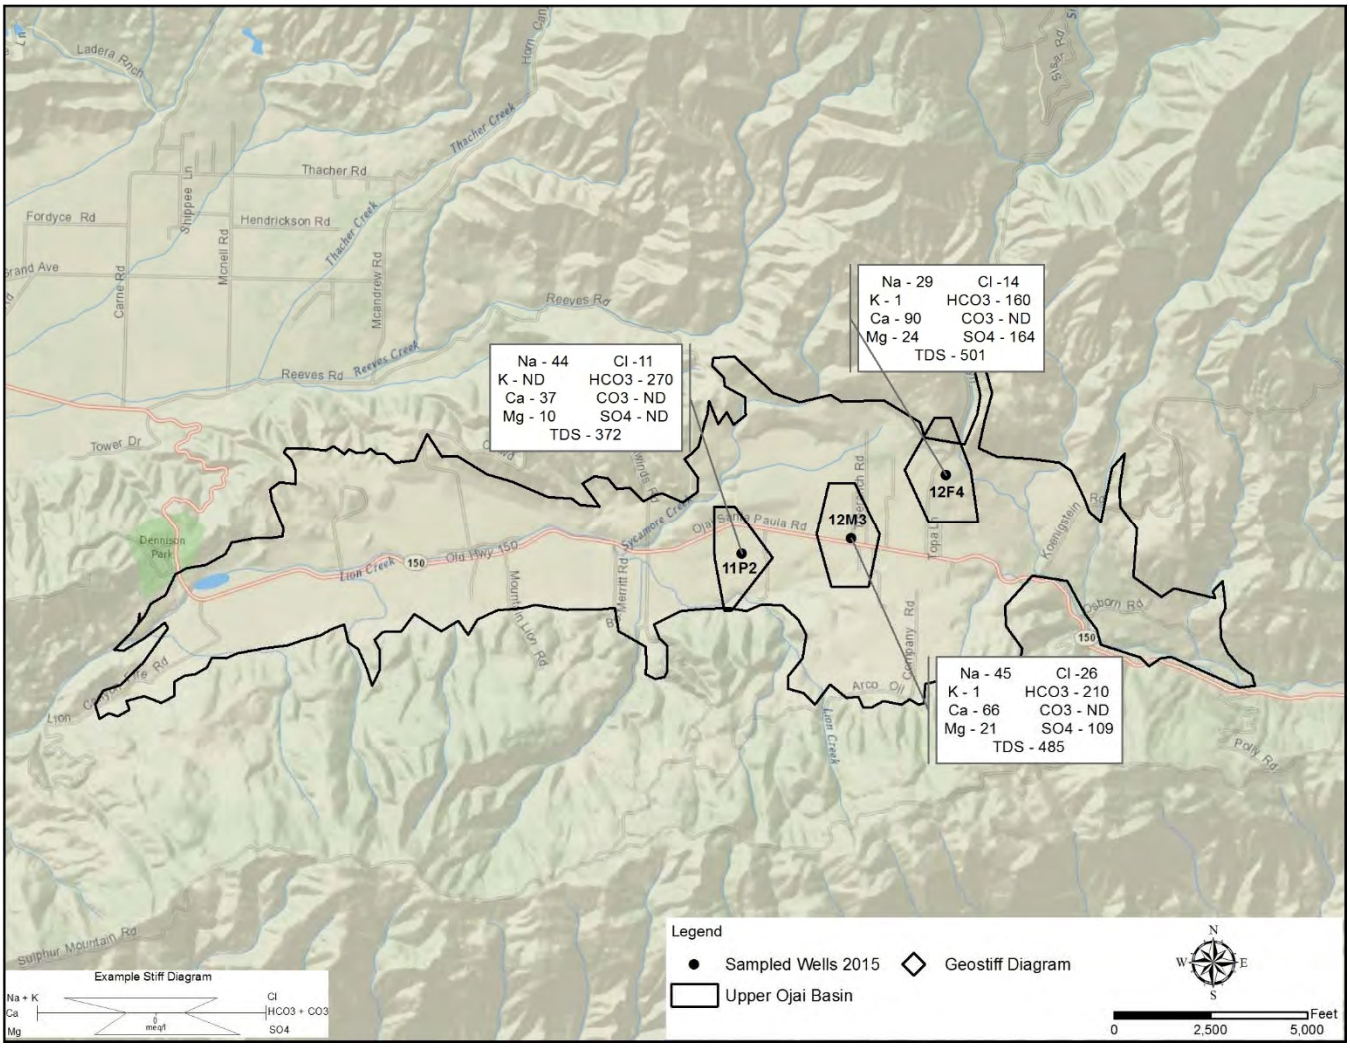

Figure 3-35: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents.

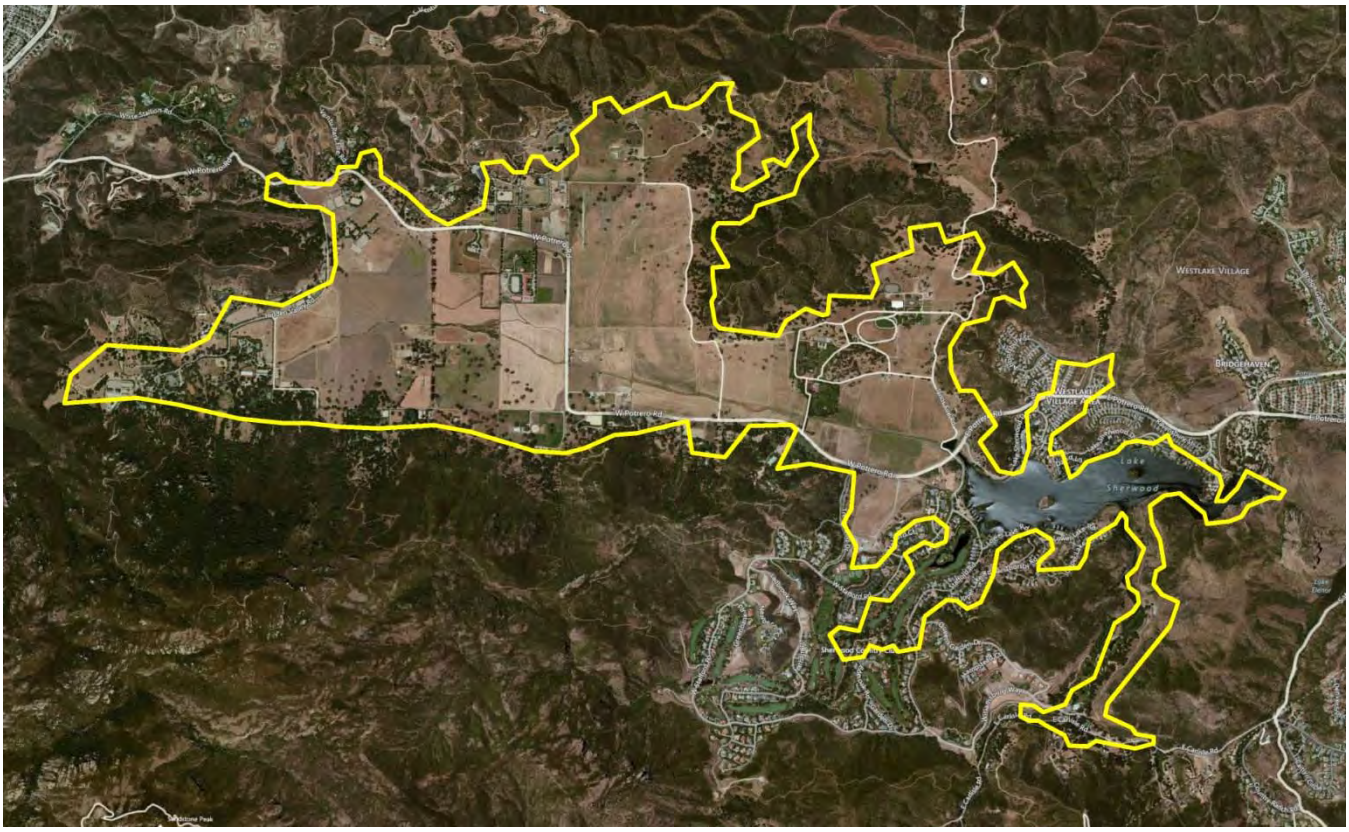
3.2.24 - Sherwood Basin

The Sherwood Basin consists mainly of fractured volcanic rock providing inconsistent groundwater supply throughout the basin because much of the water is stored in fractures. The water quality varies because of the heterogeneous nature of the aquifer. There are approximately 156 water supply wells in the Sherwood Basin; 100 are active. Four wells were sampled and analyzed this year. Figure E-40, piper diagram, shows moderate variation in the water quality of the wells sampled this year. Calcium is the dominant cation in two samples; sodium potassium group in one sample and there is no dominant cation in the remaining sample. Bicarbonate is the dominant anion in two samples, and two samples have no dominant anion. The water is calcium sulfate type in two samples, calcium bicarbonate type in one sample, and sodium bicarbonate in the remaining sample.

Iron (Fe) is above the secondary MCL in two wells; manganese (Mn^{+}) and sulfate (SO_4^{2-}) are above the secondary MCL in one well; and TDS is above the secondary MCL in three wells. TDS concentrations range from 374 to 1060 mg/l for wells sampled this season. Water samples from two wells were analyzed for Title 22 metals. Lead concentration in one well was above the primary MCL for drinking water. No other Title 22 metal was above the primary MCL for drinking water. Figure 3-36 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^{+}), potassium (K^{+}), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^{-}), bicarbonate (HCO_3^{-}), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the wells sampled in the Sherwood basin.



Aerial photo showing the extent of the Lake Sherwood groundwater basin.

SHERWOOD BASIN

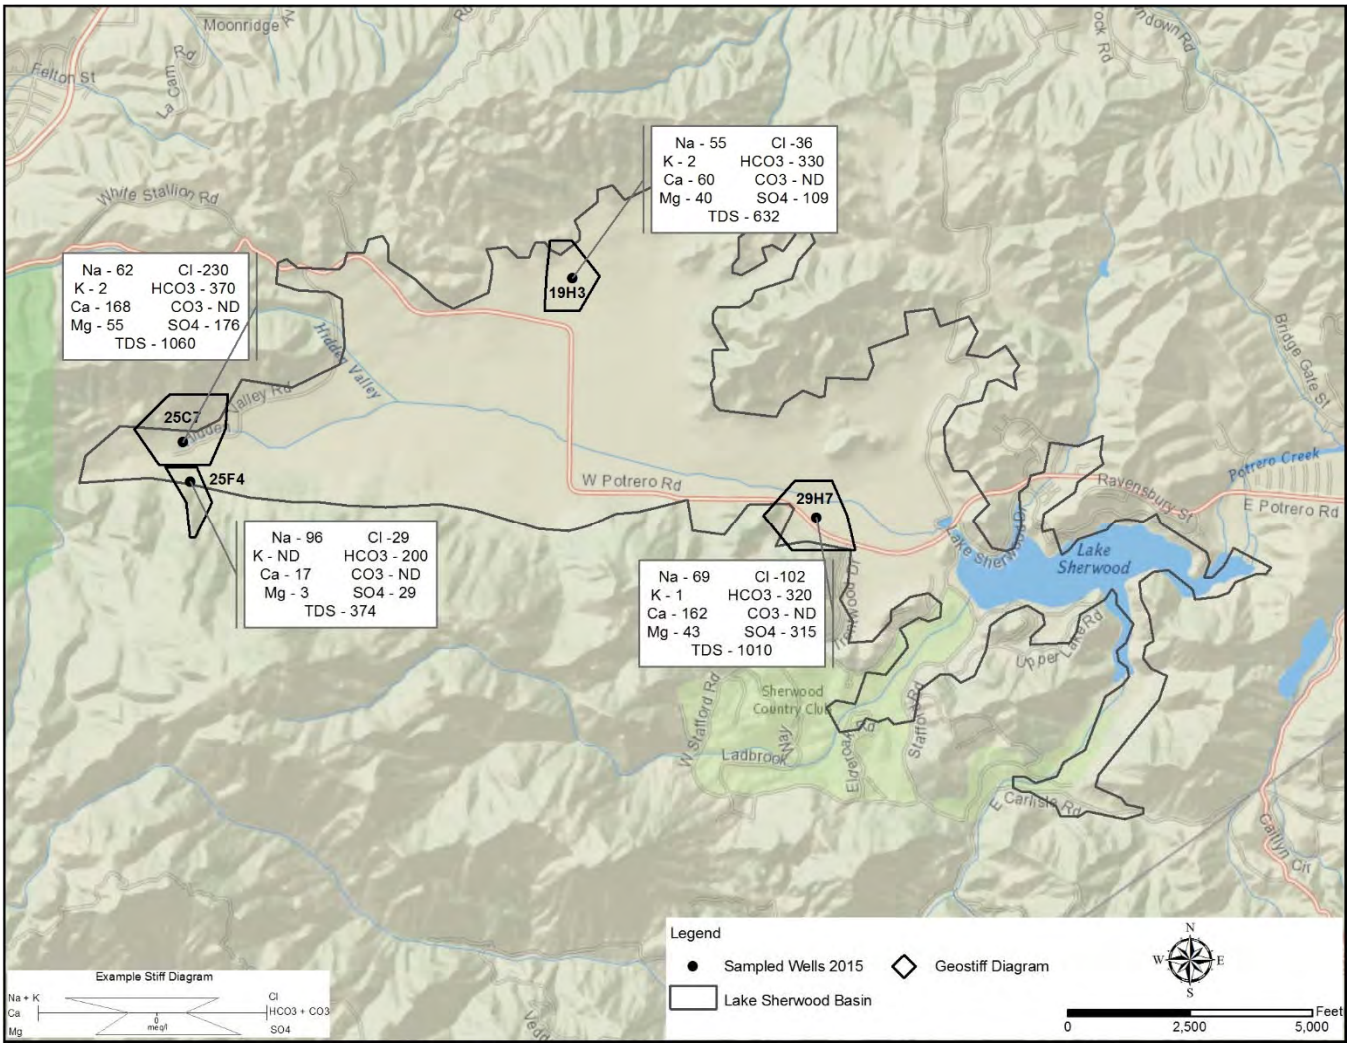


Figure 3-36: Map showing approximate location of sampled wells with concentrations (mg/l) of selected inorganic constituents.

3.2.25 - Little Cuddy Valley Basin

The Little Cuddy Valley Basin is located in the northeastern part of Ventura County near the Kern County Line. Groundwater bearing layers consist of permeable sediment lenses in the Quaternary and Tertiary rocks and Holocene shallow alluvium with the syncline that makes up the valley floor. Depth to water bearing material is approximately 20 to 30 feet. Historically groundwater quality has been considered very good. There are approximately 29 water supply wells in the Little Cuddy Valley Basin; 27 are active wells. One well was sampled in the basin this year. Figure E-41, piper diagram, shows the water quality of the well sampled this year. Calcium is the dominant cation and bicarbonate is the dominant anion in the sample. The water is calcium bicarbonate type. No chemical constituent is above the MCL for drinking water. The sample was analyzed for Title 22 metals and gross alpha. Lead is above the MCL for drinking water. No other Title 22 metal or radionuclide was above the MCL for drinking water. Figure 3-37 shows approximate well locations and concentrations of total dissolved solids (TDS), sodium (Na^{+}), potassium (K^{+}), calcium (Ca^{2+}), magnesium (Mg^{2+}), chloride (Cl^{-}), bicarbonate (HCO_3^{-}), carbonate (CO_3^{2-}) and sulfate (SO_4^{2-}) for the well sampled in the Little Cuddy Valley basin.

Section 4.0
Water Quantity

4.1 – Groundwater

The Groundwater Section collects groundwater elevation data in order to determine the general groundwater elevations and to determine if water in storage is increasing or decreasing. We also collaborate and share groundwater elevation data with other data collecting organizations in the County. The data is also used in certain basins to generate generalized potentiometric surface maps to determine the direction of groundwater movement. This groundwater elevation monitoring program is very important as there is no other systematic county wide groundwater elevation monitoring program in place. Without the data, groundwater elevations may not be known. Collected data is publically available and is also used by stakeholders, consultants, and other professionals.

In 2015, Groundwater staff gauged approximately 200 wells throughout the County. The County's standard well gauging procedures include:

- Contacting well owners to get approval to gauge wells,
- Verifying well pumps are off for at least 24 hours prior to gauging,
- Using a measuring device to obtain groundwater elevation data,
- Recording field data on a log sheet and any data qualifiers, and
- Entering water quality data in the database.

The County does not own or operate any of the wells gauged, except with very limited exceptions, and relies on well owner permission to access wells. The gauged wells include abandoned wells that are not in operation, and active wells that were off for at least 24 hours prior to water level gauging. The County strives to gauge many of the same wells each year, but because the County does not own the wells, it is not always able to control the wells availability for gauging. For example, wells may not be available due to temporary inaccessibility, pumping, or the well may have been destroyed. When a preferred well cannot be gauged, County staff will seek to find an alternative well to gauge. The process is flexible, but also limited because gauging the same well year after year is not always possible.

The following sub-sections describe the Groundwater Section's annual groundwater level monitoring program, involvement in the California Statewide Groundwater Elevation Monitoring (CASGEM) program, as well as, a general overview of water use in the County for 2015.

4.1.1 – CASGEM Program

The CASGEM Program was developed by the Department of Water Resources (DWR) in response to the passing of Senate Bill Number 6 in November 2009. The law directs that groundwater elevations in all basins and subbasins in California be regularly and systematically monitored, preferably by local entities, with the goal of demonstrating seasonal and long-term trends in groundwater elevations. DWR is directed to make the resulting information readily and widely available. The CASGEM program established a permanent, locally-managed system to monitor groundwater elevation in California's alluvial groundwater basins and subbasins identified in DWR Bulletin No. 118. The CASGEM program relies and builds on the many, established local long-term groundwater monitoring and management programs.

The Ventura County Watershed Protection District (VCWPD) acts as the Umbrella Monitoring Entity for Ventura County. The Groundwater Section staff collect water level data quarterly or semi-annually. The County compiles data it collects along with water level measurements taken by other agencies and uploads it to the CASGEM website a minimum of two times per year.

4.1.2 – Water Level Measurements

Groundwater Section staff, and several water districts and purveyors measure water levels in production and monitoring wells throughout the County. Changes in water levels are tracked and help determine change in storage, and to track trends in groundwater extraction and recharge. Last year, water levels were measured, by Groundwater Staff, quarterly in approximately 200 wells throughout the County. In the southern half of the County, water levels are measured four times, while in the more remote northern half, wells are monitored twice each year. “Key” wells for seventeen of the largest groundwater basins in the County have been established. A key well is a well selected as one giving the most representative data for the basin, or for a specific aquifer in a basin. Key wells are chosen based on their location in the basin, and availability of construction information and historical water level data.

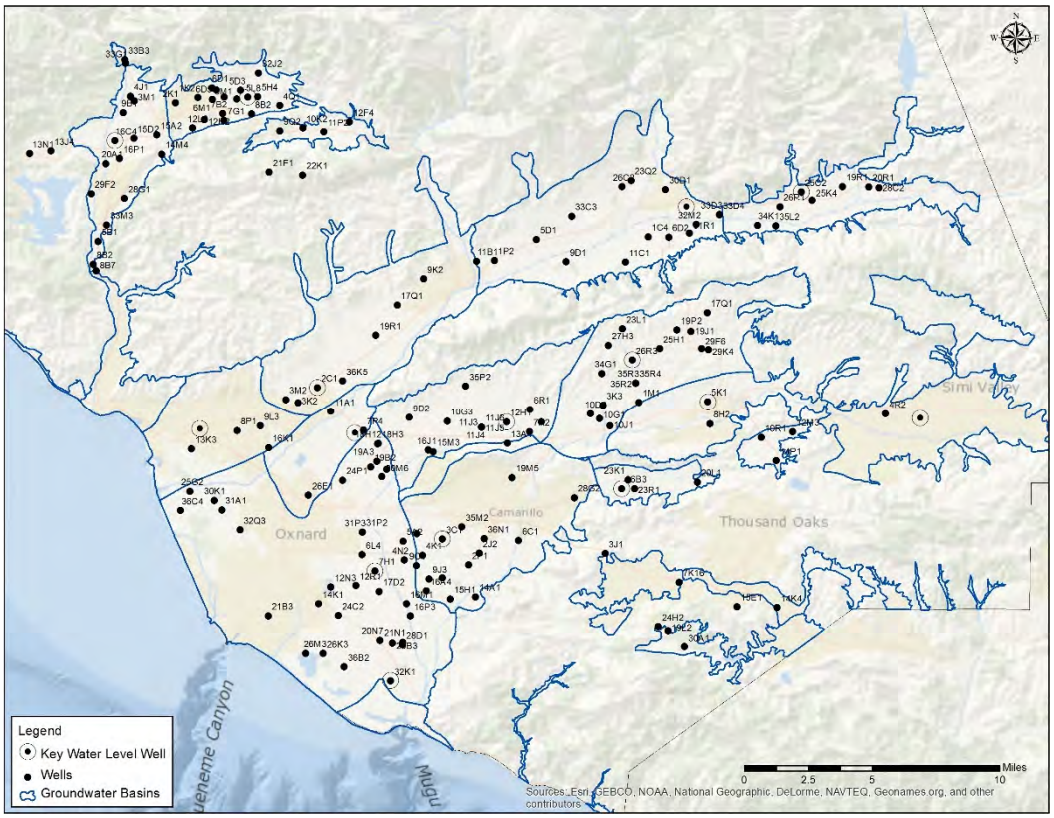

Figure 4-1: Water level wells measured in the southern half of the County.

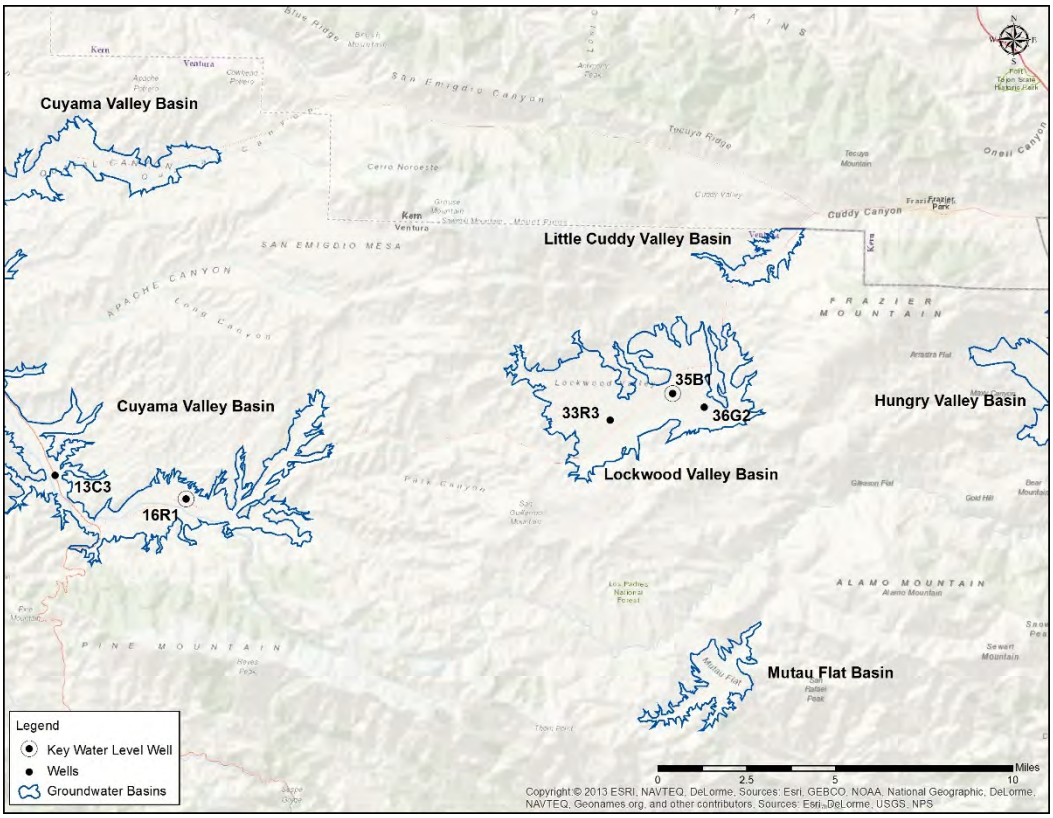

Figure 4-2: Water level wells measured in the northern half of the County.

4.1.3 – Water Level Hydrographs

The Groundwater Section maintains a database of groundwater elevations from gauged wells throughout the County. The database produces hydrographs for wells displaying groundwater elevations over time, in some cases over decades. This data along with climate, stream flow, groundwater recharge, groundwater quality and pumping data can be used to evaluate groundwater conditions in the County. Hydrographs for all "key" water level wells are shown in Appendix B. An example hydrograph for Well No. 01N21W02J02S is shown in (Figure 4-3).

Key wells are special wells the County gauges year after year to provide the most consistent data set. The Key wells were established by the County decades ago as monitoring points considered to represent groundwater elevations over a broad area of the groundwater basin.

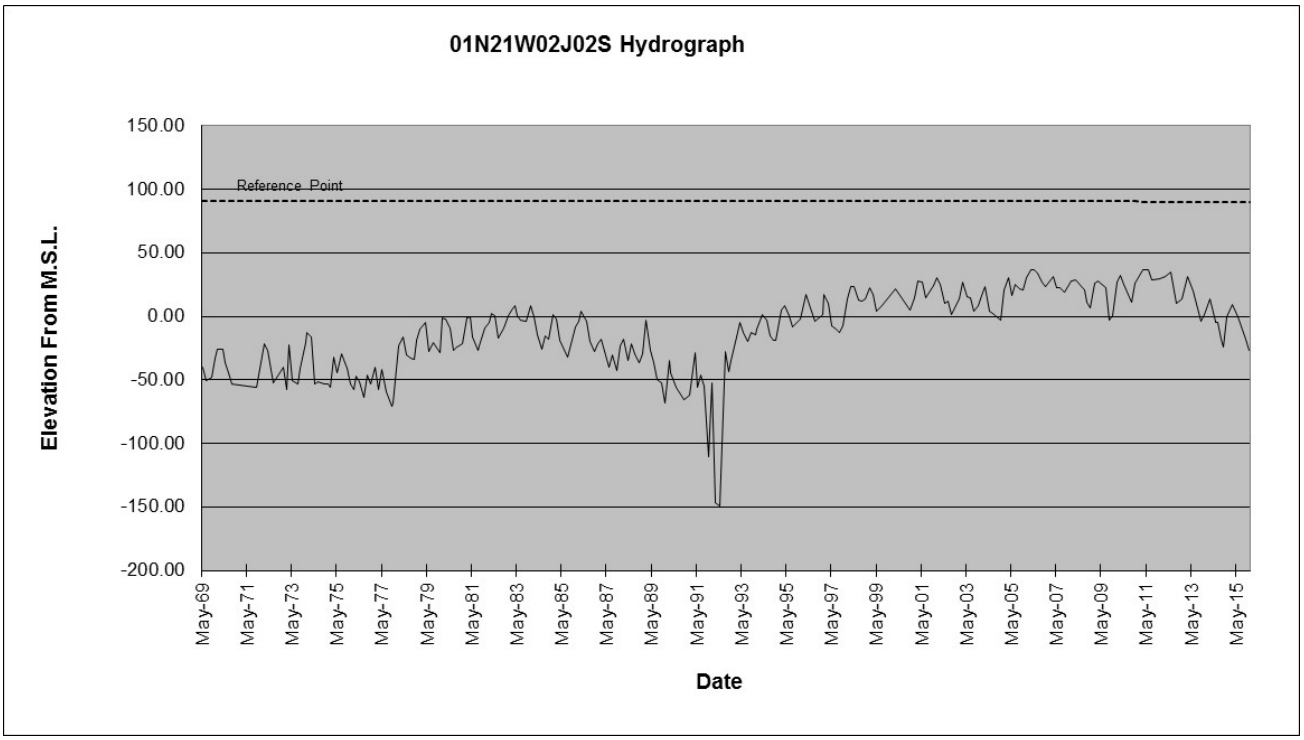

Figure 4-3: Water level hydrograph for Well No. 01N21W02J02S located in the Pleasant Valley basin.
*reference point – the elevation of the measuring point of the well.

4.1.4 – Summary of Changes to Spring Depth to Groundwater in Key Wells

The following summary is based on information gathered from key wells from major groundwater basins as shown in Table B-2 in Appendix B. The changes in water level and the water level data for the year, refer to the spring measurement (first measurement) of the year for those wells measured biannually. In general, groundwater levels in Ventura County show a downward trend due to exceptional drought conditions California is currently experiencing, and with increased reliance on groundwater resources.

The Forebay area of the Oxnard Plain, responds quickly to seasonal and annual changes in precipitation and recharge. The Forebay area key Well No. 02N22W12R01S (UWCD) is dry, meaning the water level elevation is now below the bottom most portion of the well screen. The water level elevation in the Oxnard aquifer key Well No. 01N21W07H01S was down 12.7 feet from the previous spring. The water level elevation in the Oxnard Plain Fox Canyon aquifer key Well No. 01N21W32K01S was up 7.3 feet from the 2014 spring measurement.

In the Pleasant Valley Grimes Canyon aquifer the water level elevation in key Well No. 01N21W03C01S was down 8.8 feet from the 2014 measurement.

In the Las Posas valley, the East Las Posas basin key Well No. 03N20W26R03S water level elevation was up 10.2 feet from the 2014 measurement. The water levels in this well had been declining over the previous ten year period, with the exception 2007. The water level elevation in the South Las Posas key Well No. 02N19W05K01S continued its slight upward trend of the past several years rising 3.0 feet in 2015. The depth to water in this well has risen from 136 feet to as high as 27 feet below ground surface since 1975. This trend is attributed to groundwater recharge from treated effluent from upstream waste water treatment plant discharges and groundwater discharge to surface from the Simi Valley basin. The key well for the West Las Posas basin was not measured in 2015.

In the Santa Rosa Valley the water level elevation in key Well No. 02N20W26B03S was up 3.8 feet from the 2014 measurement. The water level elevation in the Simi Valley Basin key Well No. 02N18W10A02S was up 1.2 feet from the 2014 measurement. This well has seen only slight changes in depth over the past ten years (less than plus or minus 10 feet).

In the Ojai Valley, the water level elevation in key Well No. 04N22W05L08S was down 5.1 feet from the 2014 measurement after having been down 50.2 feet from the 2013 measurement. The Ojai Valley basin responds quickly to rainfall or the lack of rainfall, and it is not uncommon to see large drops in water level during dry periods and recovery to at or above normal levels during wet periods (see Hydrograph in Appendix B). In the northern end of the Upper Ventura River Basin, the water level elevation in key Well No. 04N23W16C04S was up 13.1 feet from the measurement in 2014.

The basins that underlie the Santa Clara River valley are other areas that respond quickly to fluctuations in annual rainfall. The water level elevation in the Piru basin key well was down 14.1 feet in 2015 from 2014. The water level elevation in the Fillmore basin key well was down 3.7 feet after being down 1.9 feet the previous spring, and in the Santa Paula basin the water level elevation in the key well was down 2.7 feet from the 2014 measurement. In the Mound basin the water level elevation in key Well No. 02N22W07M02S was down 6.7 feet from the 2014 spring measurement.

In the north half of the County the Lockwood Valley basin key Well No. 08N21W35B01S was unable to be measured in the spring of 2015. The water level elevation in the Cuyama Valley basin key Well No. 07N23W16R01S was down 7.0 feet from the 2014 measurement.

4.1.5 – Groundwater Extractions

Groundwater is extracted for domestic, municipal and industrial uses, with the majority of reported groundwater extractions in the Fox Canyon Groundwater Management Agency (FCGMA) used for agricultural irrigation purposes. The FCGMA reports that approximately 60% of groundwater is extracted for agricultural purposes with the remaining 40% for municipal, industrial and domestic uses. The owners and operators of wells within the boundaries of any of the three Groundwater Management Agencies, Fox Canyon Groundwater Management Agency, Ojai Basin Groundwater Management Agency and United Water Conservation District, are required to report their groundwater extractions 2 to 4 times each year to the respective agency. Approximately 2,000 of the 3,500 plus active wells in the County are within one or more of these agency boundaries. Owners of wells located outside of these agencies are not required to report their extractions but are asked to report the status of their well to the County each year. Table 4-1 compares extractions reported to the three agencies for the years 2005 to 2015. Note: the boundaries of the FCGMA and UWCD overlap.

Table 4-1: Groundwater extractions within reporting agencies 2005-2015[3,1,2]

	Agency		
Reported Extractions (AF)	UWCD	FCGMA	OBGMA
2005-1	58,045.00	42,133.62	1,748.07

***Preliminary - Values do not reflect full reporting.

4.2 – Surface and Imported Water

The following subsections focus on water supplied and imported by the three wholesale water districts in the County: United Water Conservation District (UWCD), Casitas Municipal Water District (Casitas) and Calleguas Municipal Water District (Calleguas).

[1] Data courtesy of FCGMA.

[2] Data courtesy of OBGMA.

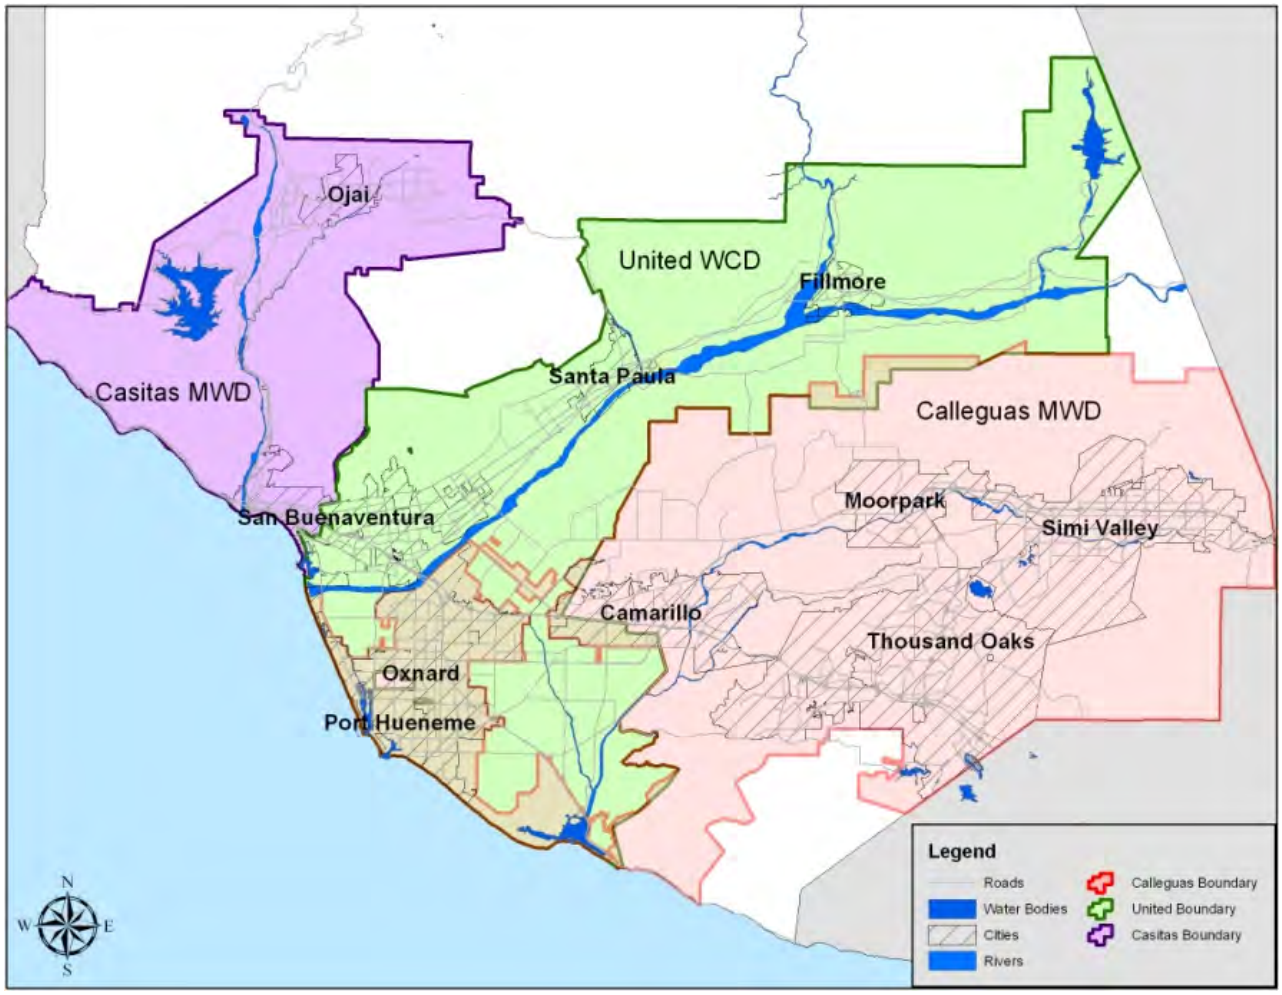

Figure 4-4: Map of the boundaries of the three wholesale water districts within the County.

4.2.1 – Surface & Imported Water Background

Of the ten incorporated cities within Ventura County only two, Santa Paula and Fillmore do not rely on water supplied by any of the three major wholesale districts (Casitas Municipal Water District, Calleguas Municipal Water District and United Water Conservation District).

Two cities (Ventura and Oxnard) use a blend of imported water, groundwater and treated surface water to meet demands. The City of Ventura's water supply comes from treated water diverted from the Ventura River, groundwater extracted from City wells, and surface water from Lake Casitas delivered by Casitas MWD. The City of Oxnard receives water from UWCD, imported water from Calleguas Municipal Water District and groundwater from City well fields.

In the south half of the County, the cities of Simi Valley, Moorpark and Thousand Oaks as well as the Communities of Bell Canyon, Newbury Park, Hidden Valley, Lake Sherwood, Oak Park and part of Westlake Village rely mainly on water imported from Calleguas.

The City of Simi Valley residents receive water from Ventura County Water Works District 8 (VCWWD8). The District extracts groundwater currently used for agricultural purposes, from three wells in the Tapo

Canyon area. Also, groundwater is extracted from several wells at the west end of the city for de-watering purposes. The water from these wells is discharged to the Arroyo Simi. The City is currently nearing completion of the Tapo Canyon Water Treatment Plant, a 1 MGD treatment plant, which will utilize the three Tapo Canyon wells to provide water to approximately 500 homes. Golden State Water Company (GSWC) in Simi Valley extracts groundwater from one well and blends it with imported water from Calleguas (10% groundwater, 90% imported water)[3]. VCWWD8 serves 68% of demand or approximately 23,000 AF of water while GSWC serves the remaining 32%, approximately 8,500 AF[4]. In 2015 Calleguas delivered 17,866[6] AF to VCWWD8 and 5,245.9[6] AF to GSWC.

The City of Moorpark residents receive water from Ventura County Water Works District 1 (VCWWD1). Approximately 75-80% of VCWWD1's water is imported from Calleguas. In 2015 Calleguas delivered 7,704.85[6] AF to VCWWD1. The City also extracts groundwater from two wells used for park irrigation.

The City of Thousand Oaks extracts groundwater using it for median irrigation on Hillcrest Ave and golf course irrigation at the Los Robles Golf Course. California Water Service and California American Water along with the City of Thousand Oaks Water Department provide water imported from Calleguas in the Thousand Oaks, Newbury Park and Westlake Village area. According to the City of Thousand Oaks 2010 Urban Water Management Plan, the City supplies water to approximately 36% of water users, California American Water 48%, and California Water Service Company 16%. In 2015 these three water purveyors received 30,966.6[6] AF of water from Calleguas.

The City of Camarillo relies on groundwater and imported water from Calleguas. The city extracts groundwater from four wells, supplying approximately 40-50% of the city's water demand with the remaining demand supplied by imported water. The city must keep its groundwater extraction volume below the groundwater extraction allocation from the Fox Canyon Groundwater Management Agency. In 2015 Calleguas delivered 4,550.43[6] AF of water to the City of Camarillo. Water for some residents is supplied by Pleasant Valley Mutual (groundwater and imported water), Crestview Mutual (groundwater and imported water), California American Water Co. (imported water), and Camrosa Water District (groundwater and imported water).

The Port Hueneme Water Agency receives and treats water from UWCD and blends it with water from Calleguas for the City of Port Hueneme, Channel Islands Beach Services Community District and Naval Base Ventura County.

In the Ojai Valley the City of Ojai and the communities of Casitas Springs, Meiners Oaks and Oak View rely on a mixture of groundwater extracted by local purveyors, and wholesale water from Lake Casitas delivered by the Casitas Municipal Water District to local water purveyors.

In the Santa Clara River Valley area, the City of Santa Paula relies on local groundwater (approximately 5,000 to 7,000 AF/yr based on reporting to UWCD). In addition, some surface water is diverted from Santa Paula Creek (approximately 500 AF/yr)[5] and is sent to Canyon Irrigation Company in exchange for extraction credits for the Santa Paula Basin. The City of Fillmore relies solely on groundwater extracted from City water wells (approximately 2,600 to 2,800 AF/yr based on reporting to UWCD). The community of Piru relies on groundwater delivered by local water purveyors.

Residents of the Lockwood Valley area and the Santa Monica Mountains area, as well as, residents living in areas not served by a water company rely on private domestic water wells. Water is extracted from groundwater basins, or from fractured volcanic rock and bedrock in areas outside of groundwater basins.

---

[4] Ventura County Waterworks District No. 8, City of Simi Valley, 2010 Urban Water Management Plan.

[5] Data from City of Santa Paula 2010 Urban Water Management Plan

4.2.2 – Wholesale Districts

Of the three water wholesalers in the County, Calleguas delivers the largest volume of water to retailers. Approximately 75% of the population in the County receives water imported by Calleguas. Calleguas, a member agency of the Metropolitan Water District (MWD), imports State Water Project (SWP) water from northern California. The Calleguas Municipal Water District imported a total of 87,794.6[6] AF of treated SWP water in 2015. Calleguas delivered 89,044.6[6] AF of water to retailers in 2015 compared to 106,293[6] AF in 2014 and 111,283[6] AF in 2013. Production from the District's ASR wellfield was 4384.18 AF in 2015. Some imported water is also injected in the East Las Posas groundwater basin through the Las Posas Aquifer Storage and Recovery (ASR) Project. In the ASR wellfield 5,372.63[6] AF of water was injected in 2015. Up to 11,000 AF of water can be stored by Calleguas in Lake Bard and can supply all of the District's needs for short periods of time. The end of year volume of water in storage in Lake Bard was 9,360[6] AF. The Las Posas Basin ASR wellfield currently has 18 wells, operated by Calleguas. The wells are 800 to 1,200 feet deep and perforate the Fox Canyon Aquifer (Calleguas 2007).

UWCD delivered 16,293[4] AF of water to retailers and end-users in 2015 down from 17,492[4] AF in 2014. UWCD can store up to 87,000 AF of water in Lake Piru. At the end of 2015 there was 11,534[4] AF of water in storage in Lake Piru. UWCD released 6,533[4] *(preliminary data)* AF of water from the lake in 2015. UWCD imported 630 AF of State Project water into Ventura County from Lake Pyramid in 2015. Water released from Lake Piru flows down Piru Creek to the Santa Clara River where it is ultimately diverted downstream at the Freeman Diversion Dam. UWCD operates spreading basins in the Oxnard Forebay Groundwater Basin for the purpose of groundwater recharge. Some of the water diverted from the Santa Clara River at the Freeman diversion is sent to the spreading basins in Saticoy and El Rio, the remainder is sent through the Pleasant Valley Pipeline (PVP) and the Pumping Trough Pipeline (PTP). Table 4-2 and Figure 4-3 compare the volume of water diverted and sent to spreading grounds by UWCD. Annual precipitation for the period of 1997 to 2015 is also shown, however recharge to basins is also a function of State Water Project deliveries and restrictions from other agencies.

Table 4-2: Comparison of precipitation versus recharge water volume by Calendar Year for UWCD[4].

CY Year	Precipitation El Rio Spreading Grounds Gage 239(in.)	Saticoy Recharge (AF)	El Rio Recharge (AF)	Noble Pit (AF)
1997	13.3	22,323.03	25,271.00	4,412.00
1998	30.88	56,934.95	43,027.00	18,710.00
1999	9.39	16,538.51	17,992.00	1,285.00
2000	15.59	28,620.11	23,173.00	0.00
2001	22.4	26,918.00	39,434.00	8,824.00
2002	8.97	5,291.00	14,886.00	32.00
2003	14.79	7,158.00	26,909.00	44.00
2004	16.13	8,105.00	15,061.00	0.00
2005	24.43	46,872.00	52,267.00	19,490.00
2006	15.29	29,005.00	40,840.00	10,709.00
2007	7.77	11,404.00	18,200.00	99.00
2008	14.07	28,631.00	19,631.00	8,562.00
2009	10.86	9,215.00	13,223.00	0.00
2010	22.07	15,108	30,125.00	995.00
2011	10.95	23,435.00	37,845.00	10,679.00
2012	8.79	3,985.00	16,293.00	538.00
2013	2.97	34.00	2,389.00	263
2014	9.5	387.00	1,935.00	578
2015	5.09	1,231.00	1,285.00	0.00

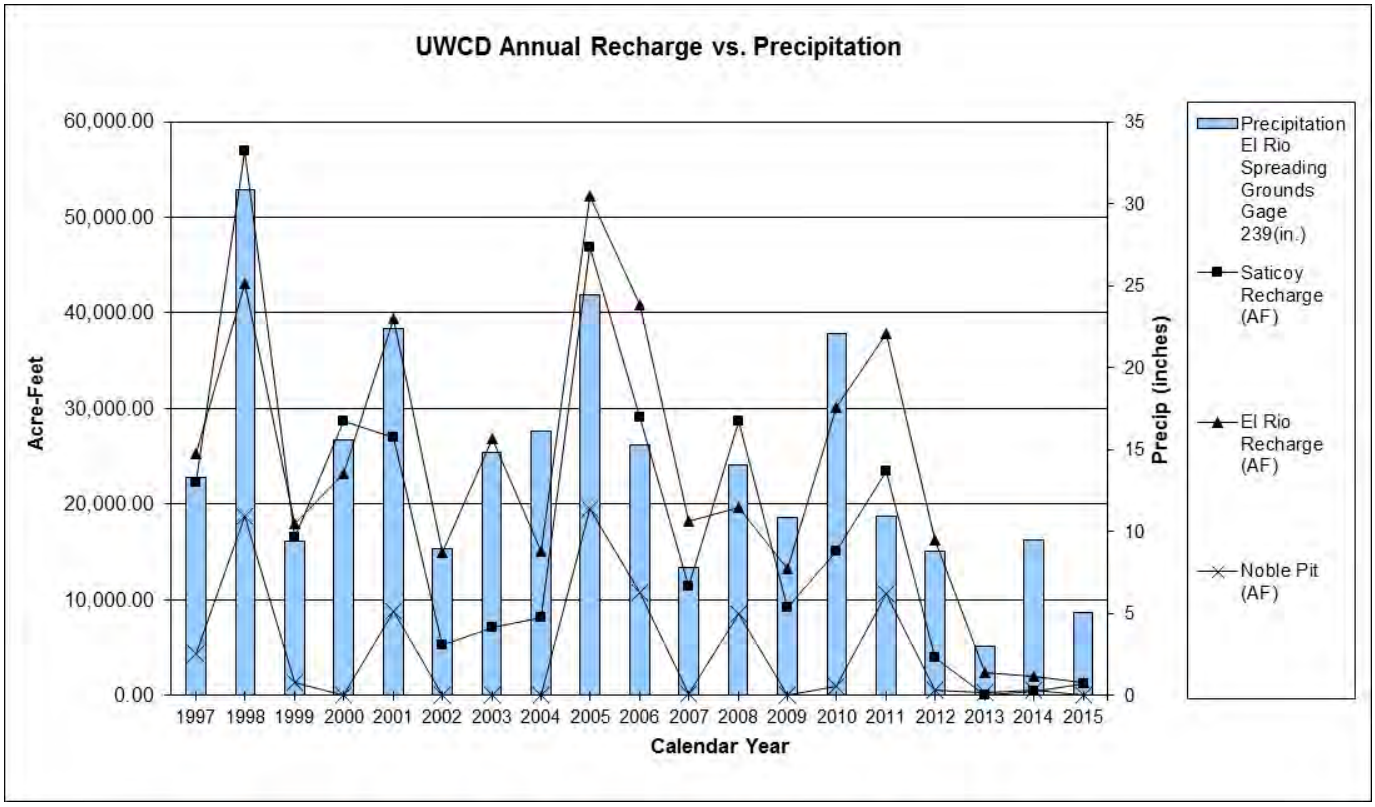

Figure 4-5: Graph depicting precipitation versus recharge for UWCD[4].

The Casitas Municipal Water District delivered 16,272[5] AF in 2015, with approximately 5,773[5] AF sold to retail water purveyors. The district provides water to residential and agricultural customers, and some of the 23 water purveyors located within the district's boundaries. Annual water deliveries can vary from 13,000 to 23,000 AF. Casitas provides a blend of groundwater and surface water to its customers. Surface water is stored in Lake Casitas which has an overall capacity of 254,000 AF. At the end of 2015 there was 103,886[5] AF of water stored in the lake. Water from the Ventura River is diverted at the Robles Diversion facility. The facility diverts high flows from rainstorms and operates on average only 53 days[5] per year. Casitas diverts, on average 31% of the Ventura River flow, with 10% of that volume being redirected downstream through the Robles Diversion Fish Passage for the endangered steelhead trout and to enhance recovery of the Ventura River habitat.

Table 4-3 below compares the volume of water delivered by the three major water districts in the County for the period of 2005 to 2015.

Table 4-3: Comparison of Wholesale District water deliveries 2005-2015.

	Total Water Deliveries in Acre Feet (AF)			
Year	**Casitas MWD**	**Calleguas MWD**	**United WCD**	**Annual Total**
2005	16,526.50	116,431.80	30,271.46	163,229.76
2006	15,873.80	120,736.30	30,627.87	167,237.97

Section 5.0
Potentiometric Surface Maps

5.1 – Mapping

Potentiometric surface maps are used to visually represent groundwater elevations over broad areas. County staff develops these maps for the Santa Clara and Calleguas Creek watersheds by assembling groundwater elevation data (from both County gauged wells and wells gauged by other organizations within the County) for spring and fall periods, inputting the data into a database and using ESRI's ArcMap GIS software, and the 3D Analyst Extension to generate potentiometric contours. The map development process is iterative. The software is used to develop the initial potentiometric surface maps. After the maps are created they are reviewed by County staff. Initial draft maps are circulated to staff, the data reviewed, adjustments made, and the maps finalized. Human input into the maps is especially important as it relates to edge of basin flowlines, selection of data, and in some cases removal of erroneous or misleading data.

5.1.1 –Maps

The following pages contain a series of potentiometric surface maps created from 2015 groundwater level data for the a) Santa Clara River Valley, b) the upper aquifer system of the Oxnard Plain and Pleasant Valley, and c) the lower aquifer system of the Oxnard Plain, Pleasant Valley, and Las Posas Valley Basins.

Figures 5-1 thru 5-2 on pages 81-82 are generalized potentiometric surface maps for 2015 for the Santa Clara River Valley area encompassing the Mound, Santa Paula, Fillmore, and Piru groundwater basins. The contours were created using data collected by County staff, United Water Conservation District staff, and the staff of other agencies, cities and water companies. For this exercise the basin area was truncated to include only the extent of the alluvial area of the valley, instead of using the full area of the basin as depicted by the groundwater basin lines on the maps.

Figures 5-3 thru 5-4 on pages 83-84 are generalized potentiometric surface maps for 2015 for the upper aquifer system of the Oxnard Plain and Pleasant Valley area. Note that the Forebay area has no confining clay cap as there is overlying the Oxnard Plain Pressure Basin, therefore the Oxnard aquifer is not recognized as being present here. In the Pleasant Valley area the upper aquifer system is not typically present, but there are areas of shallow alluvial sediments similar to Oxnard and Mugu aquifer units from which wells are extracting groundwater. Well data from the perched or semi-perched zone of the Oxnard Plain was not used to generate these contours. Some water levels represent confined conditions.

Figures 5-5 thru 5-6 on pages 85-86 are generalized groundwater potentiometric surface maps for the lower aquifer system for 2015 of the Oxnard Plain, Pleasant Valley and Las Posas Valley area. In previous reports we have used the Moorpark anticline as a boundary between the East and South Las Posas Basins to map the potentiometric surface. DWR Bulletin 118 does not divide the Las Posas Basin, but maps it as one large basin. That plus additional reports, indicate there may not be a significant groundwater flow barrier in that location. This technical issue will benefit from additional research in the future. In this report the potentiometric surface is mapped to reflect no barrier to flow between the East Las Posas Basin and the South Las Posas Basin. Data points for wells perforated in the shallow sand and gravel zones of the Las Posas Valley were not used to generate these contours.

The Groundwater Section welcomes comments and suggestions concerning the potentiometric surface maps presented on the following pages or the report in general. Please contact Jeff Dorrington at jeff.dorrington@ventura.org

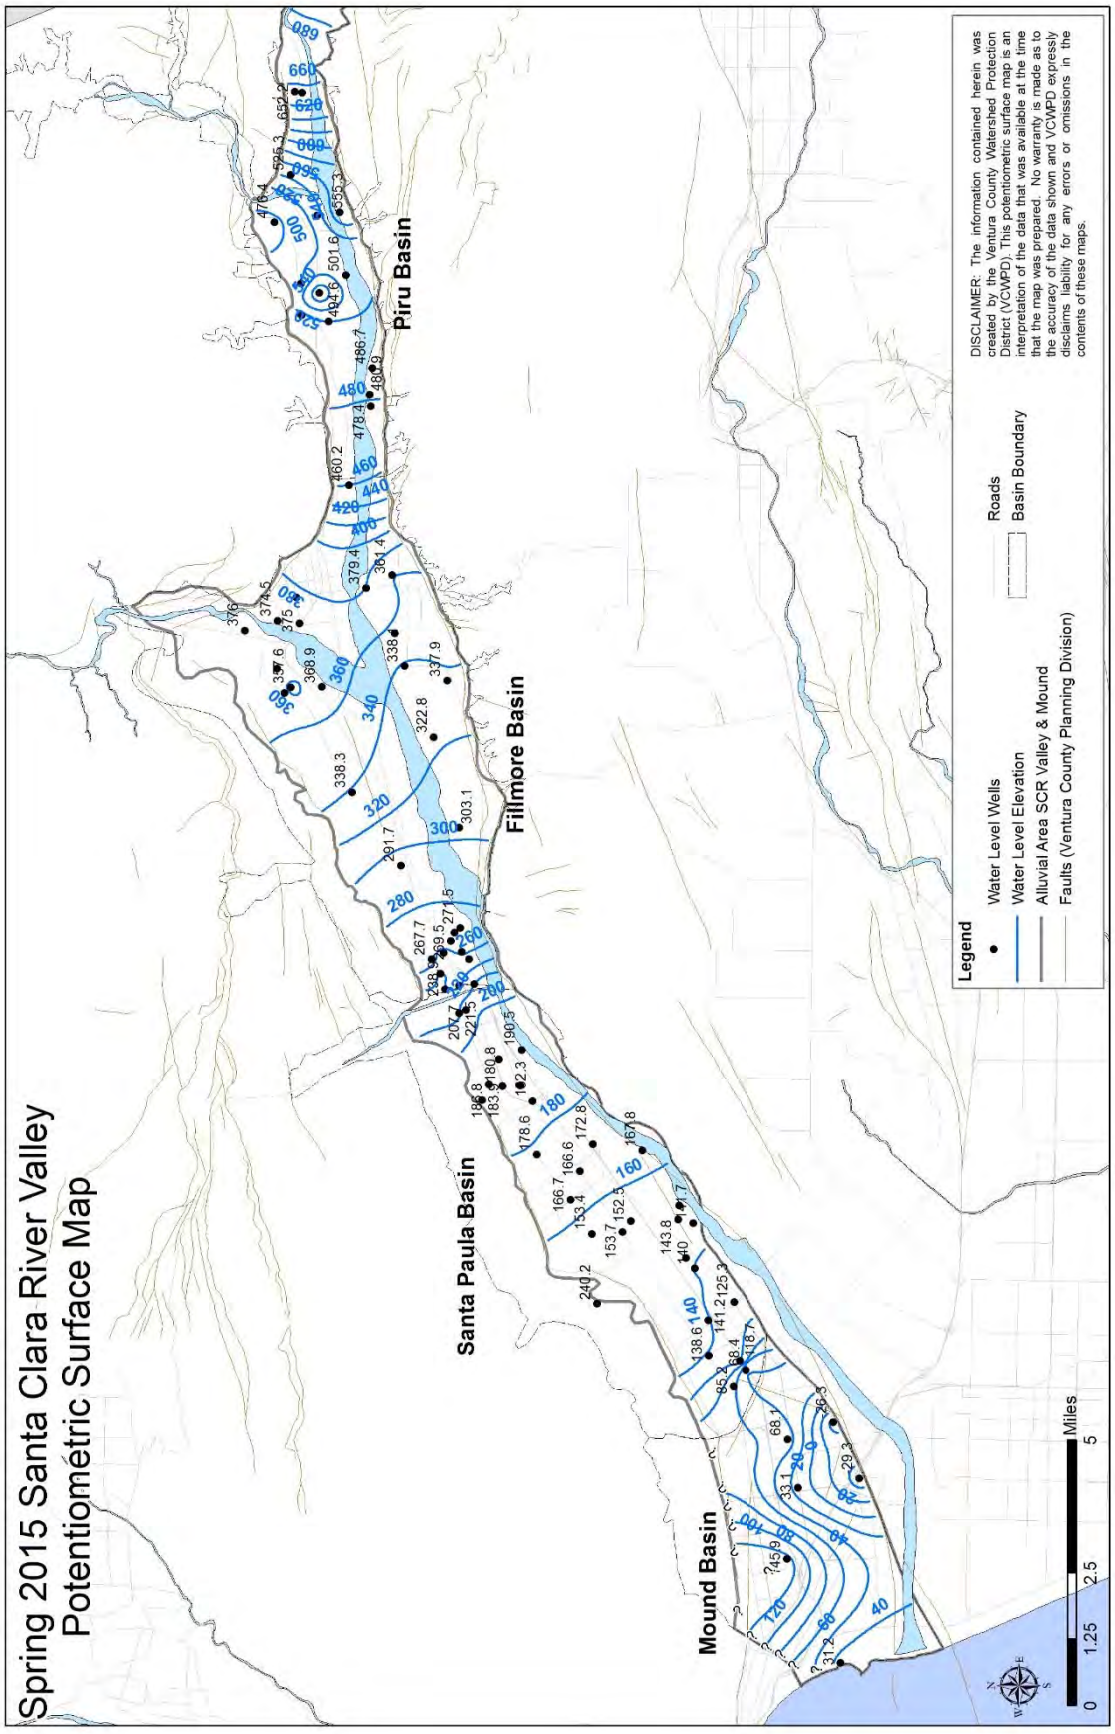

Figure 5-1: The map above depicts water level surface elevation contours for the Santa Clara River Valley area for spring 2015.

Appendix A – Glossary of Groundwater Terms

Aquifer: A geologic formation or structure that yields water in sufficient quantities to supply pumping wells or springs.

Abandoned Well: Means any of the following:

(1) A water well used less than 8 hours in any twelve-month period. Failure to submit reports of well usage will result in a well being classified as abandoned.
(2) A monitoring well from which no monitoring data has been taken for a period of two years.
(3) A well which is in such a state of disrepair that it cannot be made functional for its original use or any other use.
(4) An open engineering test hole after 24 hours has elapsed after construction and testing work has been completed on the site.
(5) A cathodic protection well which is no longer used for its intended purpose.

Confined Aquifer: An aquifer separated from the surface by an aquiclude or an aquitard to the extent that pressure can be created in the lower reaches of the aquifer.

Contamination: Alteration of waters by waste, salt-water intrusion or other materials to a degree which creates a hazard to the public health through actual or potential poisoning or through actual or potential spreading of disease.

Department of Water Resources: (DWR) operates and maintains the State Water Project, including the California Aqueduct. The department also provides dam safety and flood control services, assists local water districts in water management and conservation activities, promotes recreational opportunities, and plans for future statewide water needs.

Fox Canyon Groundwater Management Agency (FCGMA): The Agency created when the California State Legislature enacted and passed State Assembly Bill No. 2995 on Sept. 13, 1982 creating the *Fox Canyon Groundwater Management Agency (GMA)*. This law, also referred to as AB2995, granted jurisdiction over all lands overlying the Fox Canyon aquifer zone to control seawater intrusion, protect water quality, and manage water resources.

Groundwater: Water beneath the surface of the earth within the zone below the water table in which the soil is completely saturated with water.

Groundwater Basin: A geologically and hydrologically defined area containing one or more aquifers, which store and transmit water yielding significant quantities of water to extraction facilities.

Lower Aquifer System (LAS): The area underlying the Oxnard Pressure Basin, which contains the Hueneme aquifer, the Fox Canyon Aquifer and the Grimes Canyon aquifer. The LAS is recharged from the Fox Canyon and Grimes Canyon Outcrops, the areas where the aquifers come to the surface exposing the permeable sands and gravels to recharge from rainfall and surface runoff.

Overdraft: The condition of a groundwater basin or aquifer where the average annual amount of water extracted exceeds the average annual supply of water to a basin or aquifer.

Perched or Semi-Perched Aquifer: The water bearing area that is located between the earth's surface and clay deposits that exist above an Aquifer.

Appendix A – Glossary of Groundwater Terms

Receiving Waters: All waters that are "Waters of the State" within the scope of the State Water Code, including but not limited to, natural streams, creeks, rivers, reservoirs, lakes, ponds, water in vernal pools, lagoons, estuaries, bays, the Pacific Ocean, and ground water.

Seawater Intrusion: The overdrafting of aquifers, which results in, the depletion of water supplies, lowering of water levels and degradation from seawater intrusion. Seawater intrusion results from the reversal of hydrostatic pressure allowing water flow to be onshore rather than offshore.

Total Dissolved Solids: (TDS) is a term that represents the amount of all of our natural minerals that is dissolved in water.

Total Maximum Daily Load (TMDL) is a number that represents the assimilative capacity of a receiving water to absorb a pollutant. The TMDL is the sum of the individual waste-load allocations for point sources, load allocations for nonpoint sources plus an allotment for natural background loading, and a margin of safety. TMDL's can be expressed in terms of mass per time (the traditional approach) or in other ways such as toxicity or a percentage reduction or other appropriate measure relating to a state water quality objective. A TMDL is implemented by reallocating the total allowable pollution among the different pollutant sources (through the permitting process or other regulatory means) to ensure that the water quality objectives are achieved.

United Water Conservation District (UWCD): The District administers a "basin management" program for the Santa Clara Valley and Oxnard Plain, utilizing the surface flow of the Santa Clara River and its tributaries for replenishment of groundwater. Originally established as the Santa Clara River Water Conservation District in 1927.

Upper Aquifer System (UAS): The area underlying the Oxnard Pressure Basin, which contains the perched and semi-perched zones, the Oxnard aquifer zone, and the Mugu aquifer. The UAS is recharged via the twenty-three square mile unconfined Oxnard Forebay Basin near El Rio.

Water Quality Standards: Defined as the beneficial uses (e.g., swimming, fishing, municipal drinking water supply, etc.) of water and the water quality objectives adopted by the State or the United States Environmental Protection Agency to protect those uses.

Water Well Ordinance No. 4468: The Ventura County Groundwater Conservation Ordinance which was originally adopted by the Board of Supervisors in October 1970 and revised in 1979, 1984, 1985, 1987, 1991, 1999 and most recently in December 2014. The purpose of the ordinance is to ensure that all new or modified water wells, cathodic protection wells and monitoring wells are drilled by licensed water well contractors and are properly sealed so that they cannot serve as conduits for the movement of poor quality or polluted waters into useable aquifers or be hazardous to people or animals.

Well Destruction: To fill a well (including both interior and annular spaces if the well is cased) completely in such a manner that it will not produce water or act as a conduit for the transmission of water between any water-bearing formations penetrated.

Well Owner: The owner of the land on which a well is located.

Appendix B – Key Water Level Wells

Key water levels for the most significant groundwater basins are depicted on the following pages to provide visual representations of groundwater conditions over time. Note that the time duration of data may vary.

Each of the following pages is organized to describe the key water level well measured by staff. Each well listed includes a line graph (hydrograph) of groundwater levels measured in relation to the ground surface or some specific reference point (RP) which is usually the top of the well casing or the concrete slab at the wellhead. The hydrographs are accompanied by an up-down graph to track change from the previous spring.

The following summary sheet for 2015 is used by Groundwater Section Staff to track long-term trends. Spring season measurements are used for comparison since this time period is typically at the end of the seasonal and annual rainfall year when groundwater basins should be at their fullest.

Key wells were selected many years ago as representative data points based on a centralized location within any particular groundwater basin, a sufficient penetration (depth) or perforation interval within the target aquifer, proper structural or sanitary seals, adequate well construction and site access, and potential for long-term use (measurement).

These data are static water level measurements. Standard operating procedure for County Groundwater Staff is to have well pumps off for 24 hours prior to gauging.

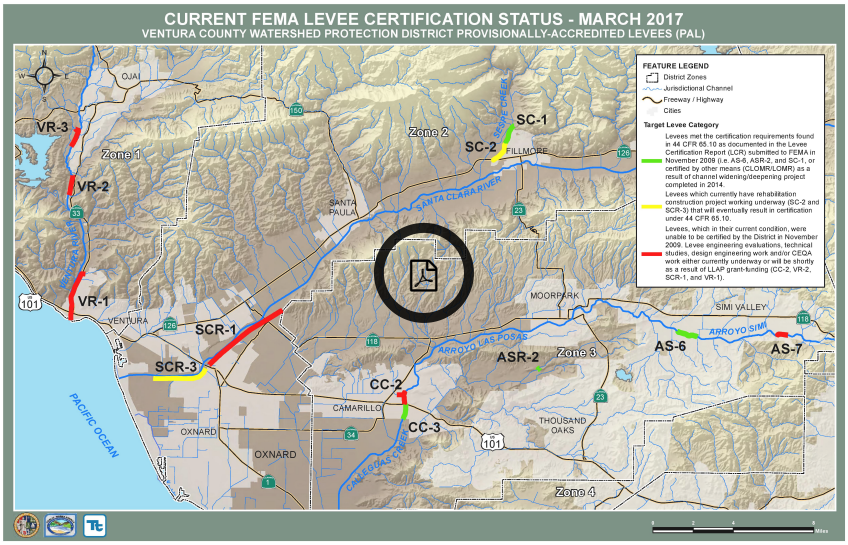
CURRENT FEMA LEVEE CERTIFICATION STATUS - MARCH 2017



FEMA Levee Certification Process Results Countywide

In November of 2009, the Ventura County Watershed Protection District completed Federally-mandated engineering evaluations of nine Provisionally Accredited Levees (PALs) located within the Calleguas Creek, Santa Clara River, and Ventura River watersheds. The maps shown above depict the most currentessential levee certification project status information regarding the aforementioned nine PAL levees.

The District submitted Levee Certification Report (LCR) compliance documentation packages to FEMA for three of the nine PAL-designated levees by November 30, 2009. They included: the ASR-2 Levee-Floodwall along Arroyo Santa Rosa in

the Unincorporated Santa Rosa Valley, the AS-6 Levee along Arroyo Simi in Simi Valley, and the SC-1 (north half of the Sespe Creek Levee) in Fillmore.

At that time, PAL-Response Reports (PRRs) were also submitted to FEMA for the remaining six PAL-designated levees. Those included: AS-7 along Arroyo Simi in Simi Valley, CC-2 and CC-3 along Calleguas Creek in Camarillo, SCR-1 along the Santa Clara River in Oxnard, VR-1 along the Ventura River in Ventura, and VR-3 in the Unincorporated Ventura River Valley. The PRRs indicated that in their then current condition, those six levees could not be certified by the District in time to meet FEMA's November 30, 2009 PAL- compliance submittal deadline date.

Subsequently, two additional levee systems, SC-2 (south half of the Sespe Creek levee in Fillmore) and the SCR-3 levee along the Santa Clara River in Oxnard, were added to the above list of levees requiring rehabilitation work to be fully compliant with Federal Levee Certification regulations [i.e. 44 CFR 65.10].

Construction of SC-2 levee improvements is concluding in September 2017, while SCR-3 levee Phase 1 construction is anticipated to end by December 2017. SCR-3 levee Phase 2 construction is anticipated to begin in September 2018 and end approximately two years later.

The cost of each of the above two levee projects has been partly offset by Proposition 84 State Local Levee Assistance Program (LLAP) Grant funding: $2.53 million for SC-2 and $5.3 million for SCR-3. The District is currently engaged in preliminary design engineering work in support of levee retrofit and/or enhancement projects required to certify the six remaining non-certified levees in full compliance with Federal Levee Certification Requirements found in 44 CFR 65.10.

In November of 2009 a planning-level estimate of the total costs required to complete the necessary levee construction rehabilitation work for all eight levees was estimated at upwards of $132 Million.. As of August 2017, VCWPD had completed approximately $40 Million of Levee Certification rehabilitation work on these levees, with an additional $20 Million programed by the end of 2020.

Currently, FEMA is engaged in the process of evaluating alternative flood-risk mapping methodologies for eventual use in the determination of Special Flood Hazard Areas (SFHA) behind non-certified levees, such as the eight mentioned above. FEMA has not yet released an official date when it plans to issue new Digital Flood Insurance Rate Maps (DFIRMs) for flood protection areas behind the Santa Clara River levees.

However, based on the latest information available to VCWPD, we believe that FEMA's projected release date for new DFIRMs for the areas behind the SCR-1 and SCR-3 levees might occur sometime during calendar year 2019 , at the earliest, possibly later.

The District is also working closely with the United States Army Corps of Engineers, as well as affected cities, residents and property owners throughout the county to marshal Federal, State and Local funding resources necessary to complete these very important levee retrofit public safety projects. Once these levee rehabilitation construction projects are completed, the District plans on submitting Conditional Letters of Map Revisions (CLOMRs) to FEMA documenting full compliance with applicable Federal Levee Certification requirements found in 44 CFR 65.10.

The District’s Levee Certification Program has been underway for ten years. At best, completion of construction rehabilitation and certification documentation for the remaining six non-certified levees will likely require at least five to ten additional years, depending on final design plans, environmental considerations, and project funding availability.

Questions regarding the District’s Levee Certification Program should be directed to Gerard Kapuscik, Manager, Strategic Resiliency Group, at (805) 648-9284 or at gerard.kapuscik@ventura.org (mailto:gerard.kapuscik@ventura.org).

VENTURA RIVER

The Ventura River and its tributaries comprise the major watershed in Flood Zone 1 comprising the west-center portion of Ventura County. Significant tributary creeks to the Ventura River include Matilija Creek, North Fork Matilija Creek, Coyote Creek, Senior Canyon, Reeves and Thacher Creeks, Lion Canyon, Coyote Creek, San Antonio Creek, and Cañada Larga. The Ventura River Watershed comprises an area of

Translate »

the City of Ventura.

Ventura River Watershed
Zone 1 (yellow)

Zone 1 boundaries incorporate two of the Supervisorial Districts for Ventura County (District 1 and District 3), with Supervisor District 1 covering a majority of the zone.

Annual weather conditions are characterized by warm summer daytime highs often tempered by ocean breezes and cool clear winter nights. Frosts are rare in the near coastal region but can be a problem for agricultural operations in inland valleys and elevated mountain portions of the watershed. Due to what is known as a "rainshadow effect", cloud systems moving inland off the Pacific Ocean soon encounter the steep mountains located only 1 to 2 miles from the coast and must discharge a majority of their contained weighted moisture before these clouds can rise to continue moving inland. This results in Zone 1 receiving the most rain in Ventura County with nearly twice the amount compared to any other area or zone.

Average annual rainfall for the drainage basin upstream of Matilija Dam is 23.9 inches per year while the average annual rainfall near the mouth of the Ventura River is approximately 16.9 inches per year. Overall average measured rain for the entire watershed is approximately 20 inches per year. Extreme seasonal variation in rainfall means over 90 percent of any given year measurement is recorded between the months of November and April. Peak historic rainfall intensity was over 4 inches per hour measured during a 15-minute period at the Wheeler Gorge rain gauge located in the mountains adjacent to Ojai Valley.

North-South crustal compression resulting from plate tectonic movements has contributed to once-horizontal rock layers being uplifted to near-vertical in many cases, and even overturned in some extreme folding or faulting situations. These highly folded mostly marine sedimentary rocks typify steep slopes in the upper portion of the watershed north of the Ojai Valley, and present significant barriers to the natural north-to-south flow direction of the Ventura River as it tries to reach the Pacific Ocean. Somewhat unique to stream systems, the Ventura River is what Geomorphologists call an "**antecedent stream"**. This is a stream that maintains its original course and pattern by downcutting at the same rate the underlying rocks are being uplifted. In this case, that's about 1/4 to 1/2 inch per year of erosion cancelling out the same amount of vertical crustal uplift.

Constant erosion rates therefore produce a large volume of sediment supplied to the Ventura River from upper-elevation tributary streams. Mass wasting from erodible, colluvial soils on hillsides, including slides, slumps, debris flows and earthflows, is a common mechanism by which sediment is transported to the river channels. Sediment production in the area is also impacted by the occurrence of more frequent than desired forest fires that burn off and clear the normally dense vegetation on slopes and flatter areas within the watershed. All that debris (rocks, boulders, sand and mud) greatly increases the erodibility and grinding of the creek bottoms and natural stream channels (US Army Corps of Engineers, 2004).

The watershed topography is characterized by rugged mountains in the upper basins transitioning to relatively flat valleys in the lower downstream areas. Over 75 percent of the Ventura River Watershed is classified as rangeland covered with shrub and brush and 20 percent of the basin is classified as forested. In general, the highest sediment-producing parts of the watershed are those covered in shrub and brush and are located in the upper parts of the watershed where slopes are greater and annual rainfall is larger. Nearly 45 percent of the watershed can be classified as mountainous, 40 percent as foothill, and 15 percent as valley area. Two major reservoirs lie within the

Translate »

There are five debris basins that collect sediment from drainages before they enter the mainstem Ventura River. Live Oak, McDonald and Dent Canyon basins are on direct tributaries of the Ventura River. There is one on Stewart Canyon, a tributary to San Antonio Creek, and another partially destroyed basin on upper San Antonio Creek. Major communities in Zone 1 include the City of Ojai, community of Oak View, and the western part of City of San Buenventura. Total population in these communities in year 2000 was approximately 22,988, excluding the western portion of the City of San Buenaventura and County inhabitants (USACE, 2004).

2021 PROGRESS REPORT – MULTI HAZARD MITIGATION PLAN (CRS ACTIVITY 510)

Date this Report was Prepared: July 20, 2021

Name of Community: County of Ventura, CA

Name of Plan: 2015 Ventura County Multi Hazard Mitigation Plan

Date of Adoption of Plan: August 2, 2016

5 Year CRS Expiration Date: August 2, 2016

Location where copies are available for review:

County of Ventura Public Works
800 S. Victoria Ave. Ventura, CA 93009
https://www.readyventuracounty.org/stay-informed/

DISCUSSION:
Communities in Ventura County face natural hazards such as earthquakes, wildfires, flooding, dam failures, landslides, debris flows, and tsunamis. The federal law known as the Disaster Mitigation Act of 2000 requires local hazard mitigation planning to reduce or eliminate the long-term risk to human life and property from natural hazards. The National Flood Insurance Program (NFIP) encourages local communities' participation in a Community Rating System (CRS) administrated by the Federal Emergency Management Agency (FEMA) to reduce or eliminate exposure to floods. Credit points are provided in CRS for the adoption and implementation of the Ventura County Multi-Hazard Mitigation Plan. Since May 1, 2016, Unincorporated County of Ventura has achieved a class 5 in the FEMA CRS rating system. The owners of floodplain properties in the unincorporated Ventura County have been receiving an annual policy premium discount of up to 25% on new and renewal policies.

The County of Ventura has adopted the FEMA-approved 2010 Multi-Hazard Mitigation Plan (MHMP) in 2011. The County, in partnership with cities, water, park and school districts, has developed a 5-year update to the 2010 MHMP in accordance with CRS requirements. The updated MHMP was completed in October 2015 and the Ventura County Board of Supervisors adopted the draft MHMP the same month. The revised MHMP went to the Board of Supervisors for re-adoption on September 13, 2016. Final approval from FEMA was received on April 10, 2017. A FEMA field verification visit was

completed on May 15, 2018, and FEMA confirmed the county's class 5 rating in the CRS program on April 1, 2021.

The next updates to the countywide MHMP is currently in progress. The Sheriff's Office of Emergency Services is managing the work with scheduled completion date of June 2022.

Per CRS requirements, the MHMP implementation progress report must be filed with FEMA on an annual basis. Since the filing of the 2020 progress report (http://bosagenda.countyofventura.org/sirepub/cache/2/utbdpeunknpilw2gnuuflh3q/15690780512202104305382 3.PDF), the following major progress has been made in the implementation of the Ventura County MHMP:

2021 Multi Hazard Mitigation Plan Annual Progress Report

1. Community Rating System
   - Prepared 2020 annual recertification and received FEMA approval in November 2020.
2. Post-Fire Flood Hazard Mapping and Debris Cleanout
   - Carried out post-fire debris flow treatments by cleaning out channels and debris basins.
3. Dam Safety and Planning for Dam Emergencies
   - Achieved approval of the remaining two (2) dam inundation mapping studies from DWR's Division of Safety of Dams (DSOD). All eight (8) state regulated dams maintained by Ventura County have approved dam break inundation maps.
   - Achieved approval of Matilija Dam Emergency Action Plan (EAP) from CalOES.
4. Hazard Mitigation Projects
   - Deploying the Flood Emergency Response grant from Department of Water Resources for upgrade to the ALERT2 flood warning systems. System update is 90% complete.
   - Conducted quarterly stakeholder meetings for Matilija Dam Ecosystem Restoration Project dam removal and levee design. Progressing towards 65% design of dam removal.
5. Levee Rehabilitation
   - Continued the design and construction of levee rehabilitation projects on Ventura River Levees (VR-1 and VR-2) and Santa Clara River Levees (SCR-1 and SCR-3).
   - Completed preliminary design for Calleguas Creek and Somis Drain Levee System (CC-2).
   - Progressed to the pre-award stage for $2.5 Million in CalOES and FEMA HMGP grant funding to support the construction of Phase II of the SCR-3 Levee Rehabilitation Project.

6. Floodplain Mapping, Flood Emergency Preparedness, and Coordination with FEMA
   - Continued cooperation and coordination with FEMA on Physical Map Revisions for Santa Clara River watershed.
   - Collaborated with FEMA to complete Physical Map Revisions for Ventura River watershed and Ventura County coast. Flood Insurance Rate Maps (FIRM) for those areas became effective on 1/29/2021.
   - Participated in California Flood Preparedness Week and conducted Storm Day emergency preparedness exercises.
   - Continued communication and coordination with FEMA to address floodplain management issues through scheduled floodplain managers' meetings.
7. Road, Bridge, and Drainage Facility Improvements
   - Awarded construction contract for Santa Ana Bridge Project.
   - Continued design of Camino Cielo Bridge replacement project.
   - Continued planning and design to rehabilitate Bridge Road Bridge (#442).
   - Completed replacement projects for bridges on Catalina Drive (Bridge #384) and Casitas Vista Road (Bridge #327).
   - Developing a Bridge Management Program to maintain County bridges.
8. Habitat Improvements
   - Continued the implementation of the Habitat Connectivity and Wildlife Corridor project.
9. Fire Hazard Reduction Program
   - Continued the implementation of Ventura County Fire Department's Fire Hazard Reduction Program.

Detailed 2021 MHMP implementation progress is reported as follows:

STATUS UPDATE OF THE MULTI-HAZARD MITIGATION PLAN

In Fiscal Year 2020-2021, the County of Ventura continued working closely with FEMA Region IX in implementing the recommended mitigation plan contained in Appendix G of the MHMP. MHMP recommendations focused primarily on flood risk mapping, levee rehabilitation with a goal to achieve FEMA levee certification, flood preparedness and storm day exercise, flood risk awareness and public outreach through annual Public Works Week, flood control channels and basins cleaning and debris removal, inspections for potential structural deficiencies and retrofitting of critical facilities and transportation systems in unincorporated Ventura County, project partnerships with FEMA, implementing vegetation management practices to protect properties from wildfires, and establishing hazard warning and public evacuation systems. Most of the recommendations are being implemented and are part of the normal business operation of the County. This demonstrates the County's ongoing commitment to providing community safety and protection from flooding and other hazards, which is a key goal of the CRS program.

The following is a list of the mitigation strategies as described in the 2015 Multi Hazard Mitigation Plan and the later section of the report will provide a detailed status update for 2021:

P1: **GIS-based Pre-application Program**
Create a GIS-based (Accela) pre-application review for new construction and major remodels in hazard areas, such as levee break, high and/or very high wildfire areas.

P2: **Integration of the 2010 HMP into Other Planning**
Integrate the 2010 HMP, in particular the hazard analysis and mitigation strategy sections, into local planning documents, including general plans, emergency operation plans, and capital improvement plans.

P3: **Seismic Retrofitting**
Seismic structural retrofit or replace County local bridges that are categorized as structurally deficient by Caltrans Bridge Inspection Report, located in an extreme ground shaking, and/or are necessary for first responders to use during an emergency. Currently in Design Phase: Bridge Road Replacement (#442).

P4: **Landslide Stabilization**
Stabilize landslide-prone areas through stability improvement measures, including interceptor drains, in situ soil piles, drained earth buttresses, sub drains, removal of slide areas, and dewatering ground.

P5: **Road, Bridge and Drainage Facility Improvements**
Reinforce and maintain County local roads, bridges, ditches and culverts from flooding through protection activities/measures.
Annual Maintenance Programs: Culvert Repair and Rehabilitation at various locations; maintenance of existing ditches and catch basins.
Improvement Projects: 1.) Mupu Road Bridge (#443) Improvements 2.) Wheeler Canyon Road Bridge (#109) Improvements 3.) Hueneme Road at Arnold Road Drainage Improvements

P6: **Address Floodplain Management Issues**
Work with FEMA Region IX to address any floodplain management issues that may have arisen/arise from the countywide DFIRM, Community Assessment Visits, and/or DWR.

P7: **CRS Participation**
Increase participation in the NFIP by entering the Community Rating System program which through enhanced floodplain management activities would allow property owners to receive a discount on their flood insurance.

P8: **Tsunami Ready Program**
Participate in the NOAA Tsunami Ready Program.

P9: **Fuel Reduction Program**
Implement a fuel reduction program, such as the collection and disposal of dead fuel, within open spaces and around critical facilities and residential structures located within a SRA or LRA high or very high wildfire zone.

P10: **Vegetation Management Program**
Create a vegetation management program that provides vegetation management services to elderly, disabled, or low-income property owners who lack the resources to remove flammable vegetation around their homes.

P11: **Post-Fire Debris Flow Treatments**
Implement post-fire debris flow hillslope and channel treatments, such as seeding, mulching, check dams, and debris racks, as needed.

P12: **Fuel Modification Program**
Implement a fuel modification program, which also includes residential maintenance requirements and enforcement, plan submittal and approval process, guidelines for planting, and a listing of undesirable plant species. Require builders and developers to submit their plans, complete with proposed fuel modification zones, to the local Fire Protection District for review and approval prior to beginning construction.

P13: **Habitat Improvements**
Work with Cooperating Agencies of Ventura River Multi-Species Habitat Conservation Plan to continue to implement mitigation measures identified in the Plan; i.e., improving habitat and/or access to habitat.

P14: **Levee Rehabilitation**
Rehabilitate eight major Ventura County levees countywide in order to document local compliance with the Federal Levee Certification regulatory requirements found in 44 CFR 65.10. Once rehabilitated and certified, these eight levees will be accredited by FEMA on Digital Flood Insurance Maps (DFIRMs) as provide flood protection from the 1% annual-chance flood event.

P15: **After Action Report and Improvement plan Development**
After every exercise or event, an After-Action Report should be completed. The After-Action Report has two components: (1) It captures observations and recommendations based on incident objects associated with the capabilities and tasks; and (2) an Improvement Plan which identifies corrective actions, assigning them to responsible parties, and establishes targets for their completion.

P16: **Life/Safety Warning/Evacuation Systems**
Implement appropriate life/safety warning/evacuation systems in Ventura County, including the Emergency Alert System, Flood Threat Recognition System, Reverse 911 System, and Tsunami Watch and Warning messages during an event or disaster.

The following are status report on each recommendation in the action plan:

P1: Create a GIS-based (Accela) pre-application

Status: The Accela Automation Land Records Management and Permit Processing/Tracking System is an interdependent electronic permit processing and tracking system that is currently being used by the Public Works Agency (PWA), Resource Management Agency (RMA), and the Ventura County Fire Protection District. It is a GIS system that integrates flood, wildfire, landslide, liquefaction, and other hazard information (mapping) with land- use planning, transportation, site grading, and other County permit processes. Accela enables County staff to access a single, common, and comprehensive information data base, thereby improving the delivery of permit-related services, including technical reviews and approvals, code enforcement, and issuance of land-use development entitlements.

P2: Integrate the 2010 HMP into other planning

Status: In 2020-2021, RMA completed the 2040 General Plan Update which integrates hazard mitigation plan recommendations into policy. PWA's 5-year Capital Improvement Plan continued to emphasize the integration of the HMP recommendations. The County Fire Protection District continued its implementation of the Fire Hazard Reduction Program (FHRP) which is the cornerstone of the Wildland Fire Action Plan.

P3: Seismic Retrofitting

Status: In 2011, the PWA Roads and Transportation (VCPWA-RT) received a $150,000 grant from the Federal Highway Bridge Program to prepare a scope of work for any repairs or replacements needed for three bridges that have been classified by Caltrans as structurally deficient (Bridge Road, Mupu Road, and Wheeler Canyon). The Scope of Work was completed in 2013. The recommended work is as follows: (1) Bridge Road Bridge (#442) rehabilitation/replacement; (2) Mupu Road Bridge and Wheeler Canyon Road rehabilitation. In 2020-2021, the Bridge Road Bridge Rehabilitation project continued moving forward with an estimated construction completion date in 2023. Mupu Road Bridge and Wheeler Canyon Road Bridge were completed in 2016 - 2017.

P4: Landslide Stabilization

Status: PWA Development and Inspection Services regularly receives private development projects relative to grading, soils, and geology (seismic, liquefaction). Plan checking, imposing conditions of development, construction compliance and enforcement are implemented as part of the grading and building permit application and approval process.

P5: Road, Bridge and Drainage Facility Improvements

Status: VCPWA-RT conducts annual ditch cleaning and culvert cleaning before winter storm season to maintain the capacity of ditches and proper drainage flow to mitigate roadway flooding in rural areas of the county. In addition to the annual cleaning of ditches and culverts, the VCPWA-RT is actively working to rehabilitate Bridge Road

Bridge (#442) which is currently in design and environmental permitting phase and is expected to be completed in 2023. Replacement of Catalina Drive Bridge (#384) was completed in May 2020 and replacement of Casitas Vista Road Bridge (#327) was completed in September 2020. Mupu Road Bridge and the Wheeler Canyon Road Bridge improvements projects were completed in 2016-2017. The VCPWA-RT is developing a Bridge Management Program to maintain County bridges. The program will identify and prioritize VCPWA-RT's 158 bridge structures which include 81 bridges on the National Bridge Inventory (NBI) and 77 non-NBI structures. This program will identify budget needs, and schedules for preventive maintenance as well as budget for required rehabilitation or replacement of VCPWA-RT maintained bridges for short and long-term planning needs. The Bridge Management Program is expected to be completed in calendar year 2021. In 2020-2021, the PWA-Watershed Protection (VCPWA-WP) continues to clean flood control channels and catch basins to prepare for winter storm seasons. The VCPWA-WP also secured Proposition 1 grant funding for Santa Ana Bridge and Camino Cielo Bridge replacement projects. The design of Camino Cielo Bridge is progressing towards 30% millstone. For Santa Ana Bridge, the construction contract was awarded in March 2021 with an estimated completion date of December 2022.

P6: Address Floodplain Management issues

Status: In 2020-2021, County staff worked closely with FEMA Region IX and CA Department of Water Resources (DWR) staff on a regular basis to address floodplain management issues. In coordination with FEMA Region IX, floodplain managers from the county and cities meet quarterly to discuss and address issues facing the floodplain management communities. The County continues to work with FEMA in moving forward with the Physical Map Revisions (PMR) for Santa Clara River watershed. The mapping projects for the Ventura River watershed and the Californian Coastal Analysis and Mapping Project (CCAMP) were completed with maps effective 1/29/2021. County staff worked closely with FEMA on the public outreach for the completed mapping projects ahead of the effective dates to inform residents and encourage flood insurance. In 2020-2021, County staff worked closely with FEMA and DWR on the dam break analysis and mapping and successfully achieved approval of the dam break floodplain mapping for the remaining two (2) the eight (8) state size dams. All eight (8) state sized dams Ventura County maintains have approved inundation maps. The County staff also responded to comments from DSOD on the draft Emergency Action Plans (EAPs) and are in the process of finalizing the plans. The Emergency Action Plan for Matilija Dam has been approved by Cal-OES.

P7: CRS Participation

Status: Active and increased participation in the NFIP has resulted in the unincorporated county of Ventura being elevated to Class 5 in the CRS rating since May 1, 2016. Owners of floodplain properties in the Unincorporated Ventura County have been receiving an annual policy premium discount of up to 25% on new and renewal policies since then.

P8: Tsunami Ready Program
Status: In 2012, the County of Ventura became certified by FEMA as a Tsunami Ready Community. Approximately 70 tsunami warning signs have been installed at specified locations along the county's coastline informing residents and visitors about the hazard.

P9: Fuel Reduction Program
Status: The Ventura County Fire Protection District annually implements fuel reduction and public outreach programs that benefit all residents through the unincorporated Ventura County. The fire department sends out a “Notice to Abate Fire Hazard” annually to affected property owners. Those property owners are expected to maintain their property free of hazards or nuisance vegetation year-round. Common requirements are 100-feet of vegetation clearance from structures and 10-feet for road access.

P10: Vegetation Management Program
Status: The Ventura County Fire Protection District utilizes a wide variety of methods and programs to reduce the effects of wildfires. The Fire Hazard Reduction Program is the cornerstone of the County’s Wildland Fire Action Plan. Property owners included in the program receive an annual "Notice to Abate Fire Hazard" and are expected to maintain their property free of fire hazards or nuisance vegetation year-round. The program has been used as a model by many jurisdictions throughout the nation.

P11: Post-Fire Debris Flow Treatments
Status: The Ventura County Fire Protection District annually implements fuel reduction and public outreach programs that benefit all residents through the unincorporated Ventura County. In 2020-2021, as watersheds continue to recover from recent fires, the VCPWA-WP continues to clean out channels, debris basins, and stop-log structures in anticipation of the next storm season.

P12: Fuel Modification Program
Status: The Ventura County Fire Protection District has established standards and guidelines, codes and ordinances to guide developments. Through the County's land-use entitlement process administered through the RMA Planning Division, the Ventura County Fire Protection District reviews, comments, and imposes conditions of approval on all development applications, including but not limited to, maintenance requirements, required plantings, and establishment of fuel modification zones.

P13: Habitat Improvements
Status: During 2020-2021, the County continued working on the giant reed (Arundo donax) and other target species removal in the Ventura River watershed with their grant partners. PWA-WP also conducted biological monitoring, water quality monitoring, and reporting. The RMA continues to enforce the Habitat Connectivity and Wildlife Corridors passed by the Board of Supervisors in 2019.

P14: Levee Rehabilitation

Status: During 2020-2021, the County of Ventura, working in close coordination with federal and state agencies, continued to advance progress in the design engineering and environmental permitting, and in some cases, the construction of projects required to rehabilitate levees owned by the County. A DWR Local Levee Assistance Program (LLAP) grant provided funding for the hydrologic and hydraulic analysis, geologic investigation, and alternative analysis for the preliminary design of the rehabilitation of the Calleguas Creek and Somis Drain Levee System (CC-2) in the City of Camarillo, and for the Ventura River Levee (VR-2) in the unincorporated community of Casitas Springs, which will ultimately lead to certification of these levees by the County, and accreditation of that certification by FEMA. The predesign study for CC-2 was completed in March 2021. That LLAP grant also provided funding to advance design engineering work, CEQA report preparation, and required environmental permitting approvals for both the Santa Clara River Levee (SCR-1) in Oxnard, and the Ventura River Levee (VR-1) in Ventura. Finally, the Sespe Creek Levee (SC-2) rehabilitation from HWY 126 to Old Telegraph Road was completed in the fall of 2017. Phase I levee rehabilitation construction work required to support the eventual certification of the Santa Clara River Levee (SCR-3) in Oxnard was completed by the County in June of 2018. The phase II of SCR-3 is planned to be constructed in 2021-2022 fiscal year. Ongoing coordination between the County and the USACE, under the Section 408 Permit envelope, is underway for both the SCR-1 and VR-1 levees. For VR-1, the County submitted 60% design plans to USACE for review in early 2021.

The County continues to work closely with the USACE, as well as affected cities, residents and property owners protected by County levees throughout Ventura County, in order to marshal federal, state and local funding resources necessary to complete local levee rehabilitation projects.

Once levee rehabilitation projects are successfully completed for the above-mentioned levees, the County will be able to document full compliance with all applicable federal levee certification requirements found in Title 44 CFR 65.10 for all of these County owned and operated levees.

P15: After Action Report and Improvement Plan Development

Status: The Sheriff's OES submits After Action Reports to state and federal agencies following all emergency occurrences. On October 8, 12, 14, and 15, 2020, the County's Public Works Agency in collaboration with County Sheriff's OES conducted its annual storm day exercise to test the overall effectiveness and efficiency of its flood warning and response procedures, technologies, communication networking, and other operational services associated with the County's Flood Warning & Response System. The exercise was modified and conducted over several days to limit gatherings while still providing valuable field training and system tests. A storm day exercise report was prepared to document observations and recommendations for future improvements.

P16: Life/Safety Warning/Evacuation Systems

Status: Ventura County uses various systems to communicate important life/safety information during an emergency. The two primary systems responsible for the bulk of emergency notifications are the Emergency Alert System (EAS) and the "Ventura County Emergency Alert Notification System."

The Emergency Alert Notification System is a joint effort among local radio and TV stations, the National Weather Service, and the Ventura County Sheriff's Office. Emergency managers can interrupt regular cable television and radio broadcast programming with important information. Locally, 100.7 KHAY FM, KMLA 103.7 FM (Spanish) and 1590 KVTA AM all carry emergency alert system broadcasts.

In addition to the Emergency Alert Notification System, the Sheriff's OES in conjunction with all Ventura County Cities operates and maintains the VC Alert Emergency Notification System. VC Alert is housed in various powerful data centers throughout the United States and is capable of sending out 100,000 text messages per hour and 100,000 e-mails per hour. The system contains listed and unlisted land lines telephone numbers, in addition to thousands of Ventura County residents who have provided their personal cell phone numbers and e-mail addresses for notification purposes.

IMPLEMENTATION:

At this time all strategies for Ventura County listed in the 2015 Multi Hazard Mitigation Plan are on schedule.

RECOMMENDATIONS:

There are no recommendations for any new projects or revisions to the Plan. However, the plan is undergoing a regular update. Progress on new projects and recommendations will be reported in the 2022 Progress Report.

Contact VCPWA – WP

The Ventura County Public Works Agency – Watershed Protection (VCPWA – WP) is soliciting input from reviewing agencies and the public regarding the scope and content of the EIR. In accordance with CEQA, Watershed Protection requests that agencies review the Project Description provided in this NOP and provide comments on environmental issues related to the statutory responsibilities of the agency. The EIR will be used by Watershed Protection when considering approval of the proposed project and by other Responsible and Trustee Agencies to support their discretionary actions related to the proposed project. Watershed Protection is also seeking the views of residents, property owners, and the public regarding issues that should be addressed in the EIR.

The proposed project would involve structural improvements to the existing VR-1 levee, which would achieve compliance with the Federal Emergency Management Agency (FEMA) levee certification requirements and United States Army Corps of Engineers (Corps) levee permit requirements, address structural deficiencies, and extend the levee's capital service life. In 2008, FEMA determined that the VR-1 levee did not fully comply with all the federal levee certification regulatory requirements. Additionally, the Corps rated the levee as "minimally acceptable," meaning that the levee has multiple deficiencies. These deficiencies put the levee at risk of failing from a one percent annual chance (also known as the 100-year) flood event. The proposed project would improve flood protection to residents and businesses in the City of San Buenaventura (commonly known as Ventura) located within the one percent annual chance flood zone (a.k.a. FEMA flood zone) by achieving a one percent annual chance flood capacity with 3 feet of freeboard (i.e., the height of the levee above the flood water).

Water Sources

Overview | Lake Casitas | Ventura River | Groundwater Basins | Recycled Water

The City of Ventura currently relies on 100% local water sources including surface and groundwater from Lake Casitas, Ventura River, three groundwater basins, and recycled water.

For an annual look at Ventura's water supply and demand status, see the Comprehensive Water Resources Reports (CWRRs). Council approved the first CWRR in June 2013, which was prepared to provide a short-term balance of water supply and demand, a predictable use of data to serve pending and projected development projects, and to provide recommendations for long term water supply and demand policy.

For long-term resource planning, see the Urban Water Management Plans (UWMPs). The UWMP addresses historic, current, and projected water demands, supplies and conservation programs. The UWMP is published every five years and is consistent with the Water Conservation Act of 2009 (Water Code sections 10608.12 to 10608.64) and the Urban Water Management Planning Act (Water Code sections 10610 to 10656).

Hello 👋. How can we help you?

Select Language

Google Translate

Lake Casitas

Casitas Municipal Water District serves customers in the Casitas district. This area includes Ventura's westside and midtown, generally west of Mills Road. Ventura Water customers who live in the Casitas District pay an assessment annually through their property taxes. For more information, visit the Casitas' website at https://www.casitaswater.org/.

Ventura River

Ventura Water operates groundwater wells and a subsurface diversion that draw water from the Ventura River.

On September 30, 2019, the City of San Buenaventura and Santa Barbara Channelkeeper entered into a settlement agreement in the lawsuit regarding the pumping and diversion of water from the Ventura River Watershed. As part of the settlement, the City agreed to begin a Pilot Program to reduce its pumping and diversion of water from the river when flows drop during dry times to help protect species that depend on the river. The City also agreed to install two monitoring gages (above and below its Foster Park facilities) to help better evaluate water levels in the river. VR1 is located upstream of the City's wellfield and VR2 is located in Foster Park just below the subsurface dam. The gages were installed in early September 2019 and calibration was completed in December 2019.

The stream gages measure depth directly, and then based on flow and depth curves, provide flow data for each depth measured. Air is pumped from the equipment box through a conduit placed in the river bottom, and sensors measure the pressure required for an air bubble to come out of the pipe. The greater the water depth over the pipe, the more pressure is required. Following installation, a team took discharge measurements in the river, and correlated those flow measurements with water surface elevation. Multiple measurements over a range of flows were used to create a curve which depicts the relationship between flow and depth for the site.

- Data collected from the gages since installation can be viewed at: https://www.picovale.com/
- Go to the "Field Station Access" button at the upper right side of the homepage and enter the following in the Users Login fields:

Groundwater Basins

In addition to wells located on the Ventura River, Ventura Water operates groundwater wells in three groundwater basins: the Oxnard Plain Basin, Mound Basin, and Santa Paula Basin. Our production is managed by existing agencies/agreements and future groundwater supply may be impacted by the Sustainable Groundwater Management Act (SGMA). SGMA was passed by the State in 2014 to improve management of groundwater resources in California. The legislation requires that groundwater sustainability agencies (GSAs) are established for groundwater basins ranked as medium- or high- priority, indicating that the basins are at risk of overdraft and/or a decline in water quality. Once GSAs are formed, Groundwater Sustainability Plans (GSPs) must be adopted and the groundwater basin must achieve sustainability by 2042.

Google Translate

- The Fox Canyon Groundwater Management Agency is named as the GSA for the Oxnard Plain Basin (ranked as high-priority).
- The Mound Basin GSA (ranked medium-priority) meets the third Tuesday of each month. Additional information and meeting materials are available at moundbasingsa.org.
- The Santa Paula Basin is adjudicated and exempt from the GSA process.
- The Upper Ventura River Basin GSA (ranked medium-priority) meets the second Thursday of each month. For more information visit uvrgroundwater.org.

Recycled Water

Ventura Water provides recycled water from the Ventura Water Reclamation Facility for golf courses, parks and similar landscape areas. Recycled water is also available to commercial and residential customers through the Mobile Reuse Program.

VENTURA WATER

Trusted life source for generations.
