RAMP C: RISK QUANTIFICATION FRAMEWORK AND RISK SPEND EFFICIENCY

I. INTRODUCTION

This joint chapter provides an overview of the quantification methods used by Southern California Gas Company (SoCalGas) and San Diego Gas & Electric Company (SDG&E) (collectively, Companies). Within this chapter, the Companies: (1) provide an overview of the quantitative assessment used for risks and mitigations/controls throughout the RAMP Report, (2) explain the methodology used to create the multi-attribute value function (MAVF) and risk spend efficiencies (RSEs), and (3) demonstrate how RSEs are used in the Reports. The Companies have used the directives established in Decision (D.) 18-12-014 and the Settlement Agreement adopted therein (the Settlement Decision) to inform the quantification methods used in the RAMP Report, as discussed in this chapter.

II. OVERVIEW OF QUANTITATIVE ASSESSMENT

This section provides an overview of how the MAVF is applied to quantitatively assess risks throughout this Report (referred to herein as the Risk Quantification Framework), including illustrating hypothetical examples of risk scores (using the ranges displayed in the examples). The Risk Quantification Framework is used to analyze risk by estimating current risk scores (the Pre-Mitigation Risk Scores) and forecasting future risk scores if new activities are started or current ones are ceased (the Post-Mitigation Risk Scores).

- Section A provides a brief overview of the quantitative analysis used to analyze each risk, according to the Settlement Decision.
- Section B describes the requirements of the MAVF per the Settlement Decision, and how the Companies' Risk Quantification Framework was accordingly constructed.
- Section C describes the steps to apply the Risk Quantification Framework in accordance with the Settlement Decision.
- Section D shows a hypothetical example of a risk score calculation using the Risk Quantification Framework.

A. Overview and Approach

The quantitative analysis applied in the RAMP Reports is derived from the Settlement Decision, and can be outlined as follows:

- Develop an MAVF, which the Companies refer to as the Risk Quantification Framework;¹
- Consider risks as defined and scoped in the Companies' Enterprise Risk Register (ERR);²
- Compute a Safety Risk Score using the Safety Attribute of the MAVF for each risk included in the ERR;³
- For each identified risk that is required to be included in the RAMP:
 - Estimate the frequency of a risk event occurring in a given year and use that value for the Likelihood of Risk Event (LoRE);
 - Estimate the average (mean) consequences if the Risk Event were to occur;
 - Apply the average consequences to the Risk Quantification Framework to create a value known as the Consequence of Risk Event (CoRE); and
 - Multiply the values of LoRE and CoRE to determine a risk score for that risk. The result of this calculation constitutes a Pre-Mitigation Risk Score.

As required by the Settlement Decision, for planned mitigations, a resulting Pre-Mitigation Risk Score will be used: (1) to demonstrate a risk score for each risk along with a ranking, and (2) as an input into the calculations to determine the change in risk scores when a risk-reducing activity is started or ceased.

B. Risk Quantification Framework

This section presents the Risk Quantification Framework that will be used throughout the RAMP Reports, as guided by the Settlement Decision. The quantitative aspects shown in this chapter are not meant to reflect precision or a comprehensive view of risk, but rather serve as a starting point on which to build. Further, as explained below, the Risk Quantification Framework is the result of many necessary assumptions. Should those assumptions change, different results would be expected.

³ *Id.* at Attachment A, A-8 - A-9 (Step 2A).

¹ D.18-12-014 at Attachment A, A-5 – A-6 (Step 1A).

² *Id.* at Attachment A, A-7 (Step 1B).

Under the Settlement Decision, the Risk Quantification Framework requires certain "attributes," defined as "an observable aspect of a risky situation that has value or reflects a utility objective, such as safety or reliability."⁴ The attributes "should cover the reasons that a utility would undertake risk mitigation activities"⁵ and must be reflected in "the way the level of an attribute is measured or expressed."⁶ The determination of attributes is left to each utility's discretion, with the requirement that the attributes should include safety, reliability, and financial attributes.⁷ Attributes are a subset of the many criteria used to assess and manage risk.⁸

The Settlement Decision also requires construction of a scale "that converts the range of natural units ... to scaled units to specify the relative value of changes within the range, including capturing aversion to extreme outcomes or indifference over a range of outcomes."⁹ Attributes also must be assigned weights reflecting each attribute's relative importance to other identified attributes.¹⁰

The three tables below show a Risk Quantification Framework utilized in this RAMP Report. Each table shows chosen attributes and assigned weights and scales. A narrative summary of the choices examined and made in assigning values to the variables shown below (*e.g.*, attributes, scales, weights) is described in Section II.E below.

The Risk Quantification Framework (as outlined in the Settlement Decision) is a prescribed methodology that provides a data point to help inform risk-based decision making (amongst other available data points). There are numerous ways to select attributes, scaling, and weights. However, the Settlement Decision contains a prescribed methodology for selecting attributes, scaling, and weights, limiting a utility's choices in certain ways. The choices elected in accordance with the Settlement Decision's prescribed methodology should not be viewed as a precise reflection of real-world circumstances.

⁹ *Id.* at Attachment A, A-5.

¹⁰ *Id.* at Attachment A, A-6.

The Settlement Decision requires the Companies to follow six principles to construct its MAVF.¹¹ The Companies applied these six principles to arrive at the Risk Quantification Framework summarized in Table 1 below. The top-level attributes of safety, reliability, and financial are consistent with the minimum attributes required by the Settlement Decision.¹² The Stakeholder Satisfaction attribute is a new attribute being introduced by the Companies – the first attribute to be used by a utility in the state beyond the three required by the Settlement Decision. Given that "[a]ttributes are combined in a hierarchy,"¹³ the top-level attributes are further broken down into sub-attributes.¹⁴ Measurement of each sub-attribute is also required and is based on unique characteristics.¹⁵ These sub-attribute measurements are then rolled up to the top-level attribute. The combined measurement of each top-level attribute is represented in Table 1 below as the Measurement Unit. The scales contained in Table 1 also reflect the Settlement Decision's MAVF principles and were constructed to represent the relative value of changes in a range of the measured units.¹⁶ Similarly, the Companies completed a weighting process in accordance with the Settlement Decision¹⁷ to develop the weights in Table 1 below (as further described in Section III.C, *infra*).

Top-Level Attribute	Measurement Unit ¹⁸	Scale	Weight
Safety	Safety Index	0-20	60%
Reliability	Reliability Index	0 - 1	23%
Financial	\$	\$0 - \$500M	15%
Stakeholder Satisfaction	Satisfaction Index	0-100	2%

Table 1: Risk Quantification Framework Top-Level Attributes

Table 2 below shows the sub-attributes contained in the Safety top-level attribute from Table 1 above. The measured unit for each Safety sub-attribute, when combined, create a single Safety Index value that is used in Table 1 above.¹⁹ The components of the Safety Index are provided in Table 2 below.

Table 2: Risk Quantification Framework Safety Index

Safety Sub-Attributes	Value		
Fatality	1		
Serious Injury	0.25		
Acres Burned ²⁰	0.00005		

Like Table 2 above, Tables 3 and 4 show the sub-attributes that are included in the Reliability top-level attribute from Table 1 for SDG&E and SoCalGas, respectively. Each subattribute is measured by its own unit. The Companies' determination of attributes, scales and weights are explained in Section III, *infra*. When all four sub-attributes for reliability are summed together, it creates a single Reliability Index value that is used in Table 1 above.

¹⁹ MAVF Principle 1 - Attributes are combined in a hierarchy. *See* D.18-12-014 at Attachment A, A-5.

¹⁸ "Measurement Unit" used herein is the measured attribute, also analogous to "Natural Unit" per the Settlement Decision Lexicon included in D.18-12-014 at Attachment A, A-3.

²⁰ Applicable only to Wildfire Involving SDG&E Equipment.

Reliability Sub-Attribute	Measurement Unit	Scale	Weight	
Gas Meters	Number of Gas Meters Experiencing Outage	0 – 50,000 meters	25%	
Gas Curtailment	Volume of Curtailments of Natural Gas exceeding 80 million cubic feet/day	0 – 250 MMcf	25%	
Electric SAIDI	System Average Interruption Duration Index (SAIDI) minutes	0 – 100 minutes	25%	
Electric SAIFI	System Average Interruption Frequency Index (SAIFI) outages	0-1 outages	25%	

 Table 3: Risk Quantification Framework Reliability Index for SDG&E

Reliability Sub-Attribute	Measurement Unit	Scale	Weight
Gas Meters	Number of Gas Meters Experiencing Outage	0 – 100,000 meters	50%
Gas Curtailment	Volume of Curtailments of Natural Gas exceeding 250 million cubic feet/day	0 – 666 MMcf	50%

Because the Financial attribute is readily measured in dollars, sub-attributes are unnecessary for quantifying it. Similarly, the Stakeholder Satisfaction attribute is composed of only affected stakeholders; thus, sub-attributes are unnecessary.²¹

C. Application of Risk Quantification Framework

The Settlement Decision further requires that the Risk Quantification Framework use specific methods of applying statistical information. The following statistical concepts are key to understanding the Risk Quantification Framework: (a) risks are evaluated at the "risk level," as defined by the Companies' ERR; (b) each risk is evaluated for annual frequency using the risk quantification method; (c) each risk is evaluated by considering possible consequences attributed to a risk event (rather than specific scenarios); and (d) averages, or expected values, are used for LoRE and CoRE.

To calculate a risk score, there are four basic steps. First, estimate the frequency of a risk event occurring in a given year and set the LoRE to this value. If the frequency is estimated to

²¹ For further detail regarding the Stakeholder Satisfaction attribute, *see* III.E.4 below.

be less than one per year, the frequency is put into decimal form. Second, estimate the average consequence for each attribute and sub-attribute based on the range of known possible consequences. Third, use the Risk Quantification Framework to obtain a single consequence value known as the CoRE. Finally, multiply the LoRE and the CoRE to calculate the risk score. To ease readability, the risk score is multiplied by 100,000, then rounded to the nearest whole number, or decimal, if less than 1.

D. Hypothetical Example Of Risk Score Calculation Using The Risk Quantification Framework

The following example will follow steps 1 - 4 shown above. All values in this example are illustrative and not representative of a specific risk.

Example: Risk XYZ

Step 1: Estimate LoRE. Internal and external data suggest that Risk XYZ will have an average of 12 risk events per year.

Step 2: Estimate consequences of attributes. Internal and external data suggest that if a risk event were to occur for Risk XYZ, the consequences would average as follows:

- a. Fatalities: 0.02 (*i.e.*, 1 fatality for every 50 risk events)
- b. Serious Injuries: 0.1 (*i.e.*, 1 serious injury for every 10 risk events)
- c. Gas Meters: 0 meters
- d. Gas Curtailment: 0 curtailment
- e. SAIDI: 0 minutes
- f. SAIFI: 0 outages
- g. Financial: \$1.5 million from damage to property
- h. Stakeholder Satisfaction: 5 points from customer

Step 3: Estimate CoRE. Each of the estimates for each attribute/sub-attribute in Step 2 is used to generate top-level attribute scores. Those scores are then used to estimate a CoRE. The values from Step 2 are shown below in boldface type.

- a. Safety Index: (Fatalities x 1) + (Serious Injuries x 0.25) = (0.02 x 1) + (0.1 x 0.25) = 0.045
- b. Reliability Index: 0
- c. Financial: **\$1.5 million**
- d. Stakeholder Satisfaction: 5

e.
$$\text{CoRE} = \frac{Safety \, Index}{20} x \, 60\% + \frac{Reliability \, Index}{1} x \, 23\% + \frac{Financial}{$500M} x \, 15\% + \frac{Stakeholder \, Satisfaction}{100} x \, 2\% = \frac{0.045}{20} x \, 60\% + \frac{0}{1} x \, 23\% + \frac{1.5M}{$500M} x \, 15\% + \frac{5}{100} x \, 2\% = 0.0028$$

Step 4: Calculate Risk Score. Multiply LoRE x CoRE x 100,000 and round to nearest whole number. From step 1, LoRE = 12, from step 3, CoRE = 0.0028. Risk Score = $12 \times 0.0028 \times 100,000 = 3,360$. The Risk Score of Risk XYZ is 3,360.

III. MAVF CONSTRUCTION AND COMPONENTS

Under the Settlement Decision, each utility is required to create a multi-attribute value function that will be used in the RAMP Report for risk scoring.²² As stated above, the MAVF is a tool for combining potential consequences of the occurrence of a risk event to create a measurement of value. This section provides a detailed description of the construction of SoCalGas and SDG&E's MAVF, including: (1) the determination of attributes, (2) the determination of scales of attributes, (3) the determination of weights of attributes, (4) how attributes were implemented, (5) details on each of the particular attributes (Safety, Reliability, Financial, Stakeholder Satisfaction), and (6) the probabilistic aspects of the MAVF.

The Companies' MAVF construction followed the steps outlined in the Settlement Decision.²³ The process of creating the MAVF is complex and should be considered a nonperfect method to enable the comparison of diverse utility risks. The complex and multilayered process to determine an effective quantitative risk methodology to enable the comparison of a broad range of risks is iterative and continually evolving, and the value functions presented in this RAMP Report should be considered in that vein. It is important to note that the construction of the MAVF discussed herein was a single effort undertaken for both SoCalGas and SDG&E. The attributes, scales, and weighting of attributes in the MAVF were determined collectively for both Companies, given the Companies' shared assets (*e.g.*, the natural gas distribution system and IT infrastructure).

²² *Id.* at Attachment A, A-5 - A-6 (Step 1A).

²³ *Id.*

A. Determination Of Attributes

An attribute, as defined by the Settlement Decision, is "an observable aspect of a risky situation that has value or reflects a utility objective, such as safety or reliability. Changes in the levels of attributes are used to determine the consequences of a Risk Event."²⁴ Following this MAVF principle (principle 1), the Companies considered a large number of attributes for the Risk Quantification Framework. The method of attribute inclusion was: (a) create a list of potential attributes (this list was a composite of attributes from various sources such as current attributes, those discussed at CPUC workshops, potential attributes as proposed through the inquiry of internal subject matter experts (SMEs), and researching external entities); and (b) determine the ability to include such attributes by considering availability of data, consistency of data, commonality of the attributes included in this RAMP Report are not meant to represent all dimensions of risk management that occur at the Companies but are useful for the purposes of this filing, namely, to create estimated risk quantification that can assist in decision-making.

Like all aspects of the utilities' Risk Quantification Framework, the attributes used, and how they are weighted, will continue to evolve over time. The version of the Risk Quantification Framework that is presented in the RAMP filing is not intended as a final effort, but rather the current version that will undergo improvements through lessons learned and input received from various sources.

Despite thorough consideration, the Companies did not include an environmental attribute in this cycle's Risk Quantification Framework. The Companies are focused on environmental impacts and thoughtfully consider how to reduce those impacts; however, for the purposes of quantification, the Companies were unable to determine how to express an environmental attribute that would enable meaningful comparison of utility risks while meeting the standards of the Settlement Decision. There are several dimensions of impacts related to the environment, including impacts to water, soil, air, species, and cultural. Within those dimensions, there are numerous sub-dimensions. For example, air pollution can take many

²⁴ *Id.* at Attachment A, A-2.

forms, such as greenhouse gas (GHG) emissions and near-ground pollution, including exhaust from vehicles and sources that have a local impact to air quality.

In addition to the various challenges related to the scope and impacts of the environmental attributes, it is also difficult to define relative weights between each of these environmental impacts. The difficulty becomes exacerbated by the sheer number of dimensions involved. The relative weights between each of them are convoluted and contradictory. The Companies will continue to review academic and governmental research regarding the impact levels of these environmental dimensions and may include updates in future Risk Quantification Frameworks. Although the Companies were unable to include an attribute specifically addressing environmental impacts for this RAMP Report, the Risk Quantification Framework does include "Acres Burned" in the Safety attribute for SDG&E to account for the detrimental impacts from pollution to human health. On a related note, the Companies discuss their dedication to environmental concerns in SoCalGas's Energy Resilience CFF (SCG-CFF-2) and SDG&E's Climate Change Adaptation, Energy System Resilience, and Greenhouse Gas Emission Reductions CFF (SDG&E-CFF-2).

Future versions of the Risk Quantification Framework may be designed with the goal of expanding and refining the number of attributes and sub-attributes in line with other key parameters used in day-to-day decision making.

B. Scales Of Attributes

The Settlement Decision directs the utility to construct a scale that converts the range of natural units to scaled units.²⁵ While the notion of applying scales for attributes appears to be straightforward, there are many aspects to consider, especially when applying the next step of assigning weights to each scale. The Settlement Decision states that the top of the scale approximates the maximum expected results for a risk. However, the Settlement Decision also requires expected values to be used. Expected values have very different "maximum expected results" depending on each scenario used. For example, a plane crash might lead to a few hundred deaths, but the annual expected value of fatalities for a particular airline in a given year is something far less. The Companies exercised their discretion to make a reasoned decision in choosing the top end of the scales for the attributes because not all risk scenarios involving a

²⁵ *Id.* at Attachment A, A-5 - A-6 (Step 1A).

particular risk yield the same maximum expected results. As discussed in the "Weights of Attributes" section below, scales and weights are strongly connected.

C. Weights Of Attributes

1. Quantitative Notes on Weights

The weight applied to each attribute is an important step in determining risk scores. Different weights can lead to different rankings of those risks. Below is a simplified, illustrative example of sample risks that show how weights can alter results.

	Safety Score	Financial Score	Risk Score Method 1: Safety: 90% Weight Financial: 10% Weight	Risk Score Method 2: Safety: 50% Weight Financial: 50% Weight
Risk A	0.5	0.2	4700	3500
Risk B	0.2	0.6	2400	4000

Table 5: Illustrative Example of Weighting

In Table 5 above, Risk A has a risk score nearly twice as large as Risk B (4700 compared with 2400) using Method 1 (90% Safety and 10% Financial), but it has a lower risk score using Method 2. This is because Risk A has more Safety risk relative to Risk B, and a weighting that favors Safety would therefore favor Risk A. This example illustrates that choosing weights can have a significant impact on the scoring that follows. The Companies are aware that the choice of weights is not perfect for all situations; therefore, scores should be thought of as estimates, rather than precise values.

2. Methodology for Determining Weights

The Settlement Decision requires that the Safety Attribute of the MAVF have a minimum weight of 40%.²⁶ Other than that safety minimum weight requirement, the Settlement Decision gives utilities the discretion to select weights through their own internal processes. The Companies' main method for determining weights for the Risk Quantification Framework considered alignment with the Companies' Enterprise Risk Management (ERM) ERR process (described in RAMP B). Using the ERR as a starting point, initial weights were identified and considered for use in the RAMP Report. Although the ERR is more of a qualitative than quantitative view of risk, it can lend itself to numerical comparisons. In addition, an industry-leading reliability study that comments on financial equivalences with reliability was considered

²⁶ D.18-12-014, Ordering Paragraph 2 at 67-68.

in the creation of the Risk Quantification Framework weights.²⁷ The Lawrence Berkeley study considers the amount of financial loss to customers due to loss of electric power. As mentioned in more detail below, because every electric outage is unique, the study is used as a guide rather than as a source of precise equivalences. While there is not an equivalent reliability study available that is specific to financial loss to customers due to loss of natural gas, the findings in the study can be extrapolated to generally apply to all utility customers.

The use of the ERR and the reliability study led to a rough approximation of how weights might look across all four attributes. Draft versions of the scales and weights were created and run through a series of real-world events to check the results for reasonableness. Adjustments were made after the reasonableness test runs and results were internally discussed. During the internal testing and discussions, it became clear that no set of scales and weights would lead to expected results for all situations. More refinements were made, and this RAMP Report utilized a set of scales and weights that may reflect an amalgam of SME and external source views.

To summarize how weights were attained for the Risk Quantification Framework, the Companies reconciled different values and data points and considered: a) the current ERR framework, b) an electric reliability study, c) a historical comparison of gas and electric reliability impacts to society, d) scenario testing, e) input from ERM staff and leadership, f) research into other utilities and industries, g) input from personnel of varying levels (including officers) at the Companies, and h) use of rounded numbers for readability.

3. Observations when Determining Weights

This section discusses several issues the Companies encountered when determining the final weights to use for the Risk Quantification Framework.

The Risk Quantification Framework uses four attributes – safety, reliability, financial and stakeholder satisfaction. In an ideal world, the relationship between each of the four pairwise combinations (*i.e.*, reliability vs. safety, safety vs. financial, and financial vs. reliability, stakeholder satisfaction vs. reliability, financial vs. stakeholder satisfaction and safety vs. stakeholder satisfaction) would be consistent. In mathematics, the transitive property is commonly stated as "If a=b and b=c, then a=c." For multi-attribute value functions, however,

²⁷ See Ernest Orlando Lawrence Berkeley National Laboratory, *Estimated Value of Service Reliability* for Electric Utility Customers in the United States (June 2009) (Lawrence Berkeley study), available at https://certs.lbl.gov/sites/default/files/lbnl-2132e.pdf.

the transitive property is less clear. As noted above, for electric reliability, the Lawrence Berkeley study was used as a starting point to compare reliability to financial. Using that data, a blackout occurring across SDG&E's service territory for eight hours would have a financial impact to SDG&E's customers of over \$1 billion. This estimate created one pairwise combination of the attributes (reliability vs. financial). Separately, a hypothetical question was posed to determine another pairwise combination (reliability vs. safety): "Which risk event would you least like to happen, a systemwide blackout for eight hours that harms no one or a safety incident at a substation that results in an employee fatality?" The Companies prioritized the elimination of the safety incident. With the two pairwise comparisons developed, the transitive property could be applied to derive the third and fourth pairwise comparison. When doing so, the third pairwise comparison (safety vs. financial) did not follow the first two pairwise comparisons and, thus, led to unhelpful values for the remaining pairwise comparisons.

In the illustrative example mentioned above, when an eight-hour systemwide outage is considered equal to a \$1 billion financial loss, and the utility prefers to have an eight-hour systemwide outage versus the fatality of an employee, it could lead to the conclusion that the utility believes lives to be valued above \$1 billion. This example highlights the complexity of creating multi-attribute value functions that have non-transitive pairwise comparisons.

Another issue is that the Companies are not accustomed to quantifying the value (financially or otherwise) of preventing safety incidents. Safety is a priority at the Companies as well as a reflection of our culture and the Companies' core values. Attempting to find pairwise comparisons with safety and other attributes can be difficult – especially at workplaces that hold safety to be non-negotiable.

Another concept observed during the creation of the Risk Quantification Framework relates to comparing the value of preventing an incident versus the value of remediating the impact if the incident were to happen. For example, if an employee becomes injured on the job, it might take some amount of financial effort and Human Resource involvement to make sure the employee is taken care of and that the employee's group has a trained person to temporarily fill the role. The value of trying to prevent the event is not equal to the value of the expected remediation costs.

D. Attribute Units

The Settlement Decision contemplates expression of attributes in "natural units."²⁸ The natural unit of an attribute is defined as follows:

[T]he way the level of an attribute is measured or expressed. For example, the natural unit of a financial attribute may be dollars. Natural units are chosen for convenience and ease of communication and are distinct from scaled units.²⁹

The top-level attributes of safety and reliability comprise sub-attributes that are used to create Safety and Reliability indices, respectively. The Safety Index has two sub-attributes, while the Reliability Index has four sub-attributes. The measurement units chosen to represent the natural units for the sub-attributes are shown in Table 6 below. The sub-attributes within safety and reliability are used to create an index for the top-level attribute.

Attribute	Sub-Attribute	Measurement Unit	
Safety	Fatality	Number of Fatalities	
Safety	Serious Injury	Number of Serious Injuries	
Safety	Acres Burned ³⁰	Numbers of Acres Burned from a Wildfire Involving SDG&E Equipment	
Reliability	Gas Meters	Number of Gas Meters Experiencing Outage	
Reliability	Gas Curtailment	Volume of Curtailments of Natural Gas exceeding 250 million cubic feet/day	
Reliability	Electric SAIDI ³¹	System Average Interruption Duration Index (SAIDI)	
Reliability	Electric SAIFI ³²	System Average Interruption Frequency Index (SAIFI)	
Stakeholder Satisfaction	Stakeholders Satisfaction Index	Five sub-attributes measuring the satisfaction of the five stakeholder groups (customer, public, employee, government, and regulators)	

Table 6: Attributes

³¹ Applicable to SDG&E only.

³² Applicable to SDG&E only.

E. Details On Particular Attributes

1. Safety Attribute

The Safety attribute consists of a Safety Index, which is calculated by assessing its two sub-attributes for every risk except Wildfire Involving SDG&E Equipment, which takes into account the additional sub-attribute of Acres Burned. SDG&E explored the defensible notion that wildfires, which result in a significant number of acres burned, have a safety impact on the general population.³³ The Company sought to capture this impact; therefore, it included this specific sub-attribute for the Wildfire risk only. The sub-attributes included are related to data that is readily available. The relative value between Fatalities and Serious Injuries is derived from information provided through the Occupational Health & Safety Administration (OSHA) and the Federal Aviation Administration (FAA).³⁴ Fatalities each receive a score of one, and Serious Injuries receive a score of 0.25 each. A Serious Injury is generally defined as an event that requires hospitalization or a permanent disfigurement of an individual.³⁵ The sum of these three sub-attributes, where applicable, create the Safety Index, which is then used as a top-level attribute in the Risk Quantification Framework.

 Table 7: Safety Attributes

Safety Sub-Attribute	Value
Fatality	1
Serious Injury	0.25
Acres Burned ³⁶	0.00005

In the RAMP Report, safety impacts are indifferent to: (a) the cause or reason for the event that results in safety impact, (b) the characteristics of those affected, (c) the perceived fault

- ³⁵ Title 8 California Code of Regulations § 330(h).
- ³⁶ Applicable to SDG&E only.

³⁴ See United States Department of Labor, Severe Injury Reports, available at https://www.osha.gov/severeinjury/; see also United States Department of Labor, Reports of Fatalities and Catastrophes – Archive, available at https://www.osha.gov/fatalities/reports/archive; see also Federal Aviation Administration, Data & Research, available at https://www.faa.gov/data_research.

of the utilities or others, (d) the mitigating or aggravating circumstances related to any impacted person's situation, and (e) other such concerns.

2. Reliability Attribute

The Reliability attribute comprises a Reliability Index that consists of two equally weighted sub-attributes for SoCalGas and four for SDG&E. The sub-attributes with their Natural Units (Measurement Units) are shown in Table 8 below. The Reliability Index shown below is structured similarly to the overall Risk Quantification Framework and contains attributes, scales, and weights.

Reliability Sub- Attribute	Measurement Unit	Scale	Weight
Gas Meters	Number of Gas Meters Experiencing Outage	0 – 50,000 meters	25%
Gas Curtailment	Volume of Curtailments of Natural Gas exceeding 80 million cubic feet/day	0 – 250 MMcf	25%
Electric SAIDI	System Average Interruption Duration Index (SAIDI) minutes	0 - 100 minutes	25%
Electric SAIFI	System Average Interruption Frequency Index (SAIFI) outages	0-1 outage	25%

Table 9:	Reliability	Attributes	for	SoCalGas
----------	-------------	------------	-----	----------

Reliability Sub- Attribute	Measurement Unit	Scale	Weight
Gas Meters	Number of Gas Meters Experiencing Outage	0 – 100,000 meters	50%
Gas Curtailment	Volume of Curtailments of Natural Gas exceeding 250 million cubic feet/day	0 – 666 MMcf	50%

The Settlement Decision requires a utility to identify relative weights between subattributes like gas and electric reliability. Relating the gas sub-attributes to electric reliability is difficult, however, there is little industry consensus on how to do so. The rationale for the scales/weights used for the reliability attributes was therefore based on a combination of external information and internal SME judgment. "Worst case" scenarios that have occurred involving gas and electric outages were used to consider the impact from gas and electric reliability. In 1994, the Northridge earthquake affected tens of thousands of gas customers, and the Pacific Southwest blackout of 2011 affected all SDG&E's customers for several hours. As recent as 2018, the Montecito Mudslides affected thousands of gas customers. The Companies' SMEs reasoned that the respective impacts of these events could be used as a baseline to create the sub-attribute scales with the Northridge gas event approximately equaling 200 minutes of a system-wide SDG&E blackout.

The gas reliability sub-attribute of Gas Curtailment is an innovative measurement, one that the Companies believe can be useful in describing the impact to customers and society. For various reasons – such as when there is a disturbance with a major gas transmission pipeline and a coincident high demand for natural gas – there are situations when natural gas service needs to be curtailed to non-core customers. The order in which curtailments are undertaken is systematic, with a goal to prevent severe disruptions to the community. However, when large curtailments are necessary, the impact to the greater community can eventually be felt. The Companies strive to prevent all curtailments, especially those that require curtailing over 250MMcfd at SoCalGas or 80MMcfd at SDG&E. Curtailments at that higher level can impact critical infrastructure such as electric generation, major industries, and hospitals. The use of this sub-attribute helps to value the importance of keeping curtailments limited in size and duration.

In addition to considering previous historical events to estimate the potential impact of a risk event to reliability, SoCalGas and SDG&E utilized subject matter expertise. In particular, SMEs considered the probability and impact of several events occurring at once across multiple operating groups like Distribution and Transmission or Transmission and Storage. Lastly, the Companies examined peak day usages and the occurrence of critical infrastructure impacts to produce a more realistic reliability attribute both in terms of meter outages and gas curtailment.

Valuing electric reliability is a complex endeavor but requires a simplified view for the purposes of the RAMP Report. To the customer, electric reliability is a composite of at least the following items: a) having electricity when the customer wants it, b) having a high quality of electricity without flicker or dimming, c) having power restored quickly if an outage occurs, and d) having access to information about when power will be restored.

The Institute of Electrical and Electronics Engineers (IEEE) has been viewed as a leader on topics related to electric reliability. IEEE publishes a document, known as IEEE 1366-2012, that is considered the industry "best practice" for how to measure electric reliability. The IEEE 1366-2012 has twelve distinct measurements that utilities can use to express reliability, and some of those measurements have sub-measurements providing essentially infinite combinations of measurements. For example, one measurement indicates the number of customers who experience a certain number of outages in a year. That measurement can be used to evaluate customers who experience one outage, or three outages, or seven outages, and so on. The large number of possibilities of measurements is indicative of how complex the subject can be.

Within its electric reliability group, SDG&E has considered at least eight different measurements in the past few years to internally measure its reliability (SAIDI, SAIFI, Worst Circuit SAIDI, Worst Circuit SAIFI, MAIFI, CAIDI, SAIDET, and ERT).³⁷ For the Risk Quantification Framework, SAIDI and SAIFI were the sole indices used due to their widespread industry usage and their relative ease of use from a forecasting perspective. Future versions of the Risk Quantification Framework may include additional methods of valuing electric and gas reliability.

The electric reliability sub-attribute of Electric SAIDI measures the average duration of service loss for each utility's electric meters over the span of a year. SAIDI is a widely used index in the electric utility industry and is frequently used to compare utilities' performance. This index does not distinguish between the type of customer or the time of day of an electric outage.

The electric reliability sub-attribute of Electric SAIFI measures the average number of outages that each utility's electric meters experiences over the span of a year. This index does not distinguish between the type of customer or the time of day of an electric outage. For example, a SAIFI value of 0.8, means that, on average, 80% of customers served by the utility experienced an outage during a calendar year. But because SAIFI measures averages, using SAIFI alone is not enough to ascertain how many different customers experienced outages. If a utility had 100,000 meters, a SAIFI value of 0.8 could mean that 80,000 meters experienced one outage during one calendar year, or it could mean that 40,000 meters experienced two outages during one calendar year.

There is significant complexity when trying to determine appropriate scales and weights to SAIDI and SAIFI in the Risk Quantification Framework. Different outages have different

³⁷ MAIFI: Momentary Average Interruption Frequency Index; CAIDI: Customer Average Interruption Duration Index; SAIDET: SAIDI Exceeding Threshold; ERT: Estimated Restoration Time.

impacts depending on who is affected and when the outage occurred. For example, given a choice between three short outages or one long outage, a small retail store may prefer the shorter outages. Shorter outages may only temporarily affect its sales and not significantly affect its infrastructure. In contrast, a large factory may prefer one long outage, because some machinery may be negatively affected by outages, and having its equipment subjected to multiple outages could be detrimental to the factory's operations. Similarly, the impact of a three-hour electric outage at a residence would be dramatically different while cooking a Thanksgiving feast versus one while everyone at the residence is away from the home.

Although gas and electric sub-attributes give information to help understand levels of reliability risk, in the end, they are merely numbers that tell part of a story. Particularly with reliability, limited data exists to determine the equivalency of gas reliability relative to other attributes, resulting in the need to leverage electric reliability data at this time. Accordingly, there is no single combination of reliability attributes that will give the perfect answer on how to measure risk. The values shown throughout the RAMP Report should be thought of as an approximation of risk rather than a precise value.

3. Financial Attribute

The Financial attribute has no sub-attributes or index and is measured in dollars. Like the other attributes, the Financial attribute is used to estimate aspects of the impact from risk events. However, different types of costs are measured in the attribute. The two general types of costs measured include: societal damage (including physical damages, lost wages, relocation costs, etc.) and utility repair costs (labor, materials). As required by D.16-08-018, the Financial attribute does not include any direct impacts related to shareholder financial interests, such as fines to shareholders, stock price changes, changes in credit ratings, or unrecoverable legal fees.

The quantitative approach used by the Companies considered historical events as a guide for possible future impacts. But precision for the financial attribute is difficult to achieve. Risk events are rarely reported with a single summation of all financial impacts. Depending on the risk event, differing approaches were used to estimate the financial impacts. For pipeline risks, Pipeline and Hazardous Materials Safety Administration (PHMSA) data was used in combination with internal data, but the financial values provided by PHMSA do not necessarily include all financial impacts to society. For electrical outages, estimates were made for the amount of labor and cost of repair. Financial estimates are gathered from various sources including internal estimates based on claims data or work orders, third party sources, news reporting, among others. Because these data sources rarely include all financial impacts from a risk event, estimates are used.

4. Stakeholder Satisfaction Attribute

In this RAMP cycle, SoCalGas and SDG&E are the first California utilities to implement a fourth attribute – Stakeholder Satisfaction. The Stakeholder Satisfaction attribute is a qualitative approach to measuring changes in satisfaction levels to various stakeholders during and after a risk event. SoCalGas and SDG&E recognize that risk events, whether caused by or involving the Companies, have the potential to affect various stakeholders' satisfaction in varying degrees of severity over varying amounts of time. For example, a pipeline rupture involving fatalities would not only have a direct safety, financial and reliability impact for those involved, but it would be expected to result in a decrease in satisfaction to individuals and groups within the rupture's impact zone. This could result from a loss of service downstream of the rupture or potential mental health issues for individuals that were near the risk event when it occurred. Additionally, with respect to non-customer results, the root cause analysis of an event would likely lead to not only operational changes at the Companies but could even spark new regulations to prevent a similar rupture event from occurring again. The Stakeholder Satisfaction attribute is designed to take into account the above effects of a risk event that are not succinctly delineated by safety, financial and reliability impacts alone.

Table 10 below illustrates the elements that comprise the Stakeholder Satisfaction attribute.

Stakeholder Sub-Attribute	Value
Stakeholders Affected	0-100 (Up to 20 points for each of the stakeholder groups – customer, public, employee, government, and regulators.

Table 10: Stakeholder Satisfaction Attributes

Recognizing the difficulty in measuring any particular individual's or group's satisfaction (as noted above), SoCalGas and SDG&E explored various means to quantify the notion of satisfaction during or after a risk event beyond the safety, financial and reliability impacts. One path explored was measuring the satisfaction to stakeholders through public surveys or polling; however, the determination of pre- and post-activity measurements would require consistency of

individuals and/or groups for each survey or polling, and a measurement after each activity, which could be in the thousands. The Companies determined that this would be too challenging and/or imprecise. Measuring this attribute would be further complicated by the fact that satisfaction varies between individuals and groups.

Ultimately, the Stakeholder Satisfaction attribute was determined through a qualitative assessment of risk events by ERM teams and operational SMEs. This qualitative assessment takes into consideration past events both inside and outside the Companies to determine the potential satisfaction of various stakeholders and appropriately apply that to the RAMP filing in the context of the MAVF.

F. Probabilistic Information

This section will discuss the quantitative methodologies, including statistical information and how computer software was used for this RAMP Report. The Settlement Decision requires utilization of specific quantification methods. Among those methods are the creation of LoRE and CoRE values for each current risk. These two values are then multiplied together to obtain a risk score. Additionally, LoRE and CoRE are used to calculate RSEs by estimating new LoRE and CoRE when risk-reducing activities are introduced or ceased.

1. Expected Values

As mentioned above, LoRE and CoRE utilize expected values. The term "Expected Value" is a statistical term meaning the weighted average. For example, suppose there was a casino game that paid \$10 to the player 25% of the time and paid \$1 to the player the other 75% of the time. The expected value of this game would \$3.25 because \$10 * 25% + \$1 * 75% = \$3.25. The term "Expected Value" is not meant to imply that the Company expects a certain outcome. Note that in the example above, the expected value of \$3.25 can never occur, because only the values of \$10 and \$1 can be paid out. The use of expected values has known limitations in the risk management world, and great care must be taken when reviewing data that solely comprises expected values.

2. Likelihood of Risk Event (LoRE)

In the context of the Settlement Decision, the "Likelihood" is not a true likelihood in the typical statistical or probabilistic sense. In standard mathematics, a likelihood is the probability of an event occurring given a set of conditions (*e.g.*, the chance that a red jellybean is drawn from a jar of jellybeans). These standard probabilities can take a value between 0 and 1, where 0

indicates the event will never occur and 1 indicates the event will always occur. For example, in traditional terms, the probability of flipping a coin and obtaining "tails" is 0.5. The term "frequency," on the other hand, is a statistical term denoting the number of times that an event has or will occur, given a specified time frame. For purposes of the RAMP Report, the annual frequency of an event is used to estimate LoRE. An explanation of why frequency was used rather than likelihood is discussed below.

The following is an illustrative example to highlight how frequencies and likelihoods are used in the RAMP Report:

a. Example: Illustrative Gas Risk

The RAMP Report views risks at the "risk-level" over the span of a year. Suppose that a utility has an item in its ERR known as Illustrative Gas Risk. For the RAMP Report, it is necessary to determine the likelihood of that risk occurring each year. In this illustrative example, assume the following:

- The utility uses data to estimate the incident rate.
- The illustrative gas system is composed of 100 pipe segments.
- Each pipe segment has a likelihood of an event of 1/10 over a given year.
- If the pipe segment had an event, the event would cause some amount of safety, reliability, and financial impact to society and to the utility.

From a purely probabilistic point of view, and because LoRE is calculated at the risklevel, the likelihood that at least one pipe segment will have an incident in a given year is quite high (>0.999 or over 99.9%). The graph below shows the probability of the number of incidents, given the assumptions above:

For the RAMP Report, the important concept is not the *likelihood that a pipe segment will have an incident*, but rather, the number of pipe segments that are estimated to have an incident in a year. The likelihood value that is provided is the "Expected Value" of the frequency. In the example above, the expected value of pipe segments that will have an incident in a given year is determined by multiplying the number of pipe segments in the system by the likelihood of a single pipe segment incident occurring: $100 \times 1/10 = 10$. In this example, the LoRE for this system would be 10, which behaves like an estimated frequency of the number of incidents predicted in a year.

3. Consequence of Risk Event (CoRE)

The CoRE is determined by estimating each of the data points required by the Risk Quantification Framework, as discussed below. Like LoRE, the data points that inform CoRE are also expected values. For example, the number of serious injuries used in the calculations are the expected values of serious injuries if the risk event were to occur. Applying this to one of the RAMP risks, an illustrative example can be found in the SDG&E Employee Safety Risk Chapter (Chapter SDG&E-8), where potential safety consequences can theoretically range from one serious injury to several fatalities. The calculations used in the Risk Quantification Framework for that risk use the expected value of that range. In the case of Employee Safety, the expected value of the safety impact when a risk event occurs is 0.40. The expected values of each of the nine attributes and sub-attributes are used as inputs into the Risk Quantification Framework to produce a CoRE for each risk. This process was undertaken many times for each risk; once to establish the current risk score, and once for each activity where the estimates of CoRE are performed as if the risk-reducing activity has been implemented, in order to calculate RSEs. As with LoRE, the data used to compute CoRE was a combination of internal data, external data, and/or SME input, depending on the particular risk.

a. Secondary Impacts

The Companies use the term "Secondary Impacts" to distinguish between the impacts that are directly caused by a risk event and the impacts that are "downstream" of the initial risk event. Because each risk has its own definition of a risk event, it is difficult to generalize the difference between the direct impacts and secondary impacts. Table 11 below provides examples, using the Companies' different RAMP risks:

	Direct Impact	Secondary Impact
Electric Infrastructure Integrity	Person hurt due to touching fallen electrical wire	Vehicle driver failing to stop at traffic light that is not operating properly during electrical outage
Medium Pressure Gas Incident	Person hurt due to gas explosion	Customer experiencing gas outage decides to cook using a charcoal barbecue and is accidentally injured
Cybersecurity	Intruder uses remote attack to overload transformer, which subsequently explodes and harms individuals	Intruder uses remote attack to steal financial information from utility customer, which leads to additional downstream financial harm to customer

Table 11: Illustrative Examples of Secondary Impacts

Secondary impacts are generally not used in risk scoring in this RAMP Report because they are difficult to estimate and track and are not always controllable by the Companies. Data sources used for risk assessments do not consistently track secondary impacts, if tracked at all. Secondary impacts will rarely be a large driver of risk scores, even if the data was well collected. One illustrative example mentioned earlier - large electrical outages that span entire cities - could have secondary impacts, but the documented history of such events lacks sufficient data to measure that risk. SDG&E experienced a systemwide blackout in 2011 due to electrical problems outside of its service territory. The blackout caused outages in all of San Diego and Imperial counties, as well as parts of Orange County and western Arizona. The outage in SDG&E's service territory lasted nearly twelve hours, with the average customer without power for over eight hours. During that time, safety-related incidents were reported. It is clear that undesirable outcomes can occur in large electric or gas outages, but the available data is not conducive to determining expected values of impact. In future years, there may be more opportunities to determine how to effectively incorporate secondary impact information as part of risk assessments.

4. Modeling

Computer software was used for many quantitative aspects of the RAMP Report. The primary software applications used by the Companies were Microsoft Excel, Visual Basic, and @Risk. Additional work was also done with Microsoft Access, R, and Python.

Monte Carlo simulations were performed on risks. Monte Carlo analysis is a technique used to understand the impact of uncertainty related to a particular risk. Although the Settlement Decision does not specify that Monte Carlo simulations are necessary, the modeling assisted in several ways that bolstered the analysis and occasionally informed critical elements. Throughout the individual risk chapters, analytical methods are discussed, including the extent of modeling.

One of the benefits of modeling is that it can be used to demonstrate a range of outcomes that might be observed, given a set of inputs. When trying to identify ranges of outcomes or their certainty, performing Monte Carlo modeling can be easier to implement than precise statistical equations.

Considering consequence ranges is an important part of risk analysis. Consider two risks, both with an expected value of a \$10 million loss, but with very different consequence ranges. Suppose Risk A rarely occurs, but when it does, it can require \$1 billion of reparations; but, assuming it is a 1/100-year event, its expected value is \$10 million (\$1 billion x 1/100). Risk B has risk events that occur several times a year and the annual financial impact varies only slightly from \$8 million to \$12 million, with an expected value of \$10 million. Certain stakeholders may be interested to know that, despite having similar expected values, the risks have very different consequences. Creating ranges of outcomes, whether through Monte Carlo modeling or pure statistical approaches, can illuminate differences in risks.

IV. RISK SPEND EFFICIENCIES

This section addresses how RSEs are calculated in this 2021 RAMP Report. RSEs are numerical values that attempt to portray changes in risk scores per dollar spent. The change in a risk score is one data point that can help to inform decision-making and can be due to: (a) the amount of risk reduction when a new activity is completed, or (b) the amount of risk increase if a currently on-going activity is ceased.³⁸ The overall guiding principle of an RSE is that it presents the difference between the risk score over a certain span of time if the activity is undertaken versus if the activity is not undertaken. However, as discussed further in sections above and below, these data points should be viewed critically. This section: (1) illustrates how RSEs are created, with examples of RSEs for both Controls and Mitigations, (2) explains how benefits over time are treated, and (3) explains the challenges presented by RSEs.

A. Determining Risk Spend Efficiencies

As discussed in the section above, each risk has a risk score, calculated using the Risk Quantification Framework. The risk score that is developed is meant to represent the current risk situation. The current situation for each risk attempts to consider existing activities (known as Controls), current work standards, and all other current characteristics, such as asset conditions, environmental conditions, etc. A risk score is calculated by multiplying the LoRE and CoRE. The risk score that results from using the Risk Quantification Framework is the baseline used when calculating RSEs. Next, a second estimate for LoRE and CoRE that considers a change in a risk-reducing activity is estimated. For Mitigations, the second LoRE and CoRE are estimated assuming the new activity is in place. For Controls, the second LoRE and CoRE reflect the estimated risk if the activity is ceased.

For purposes of this RAMP Report, the terms "pre-mitigation LoRE"³⁹ and "premitigation CoRE" refer to the estimated risk values given current situations. The terms "postmitigation LoRE" and "post-mitigation CoRE" refer to the estimated risk values if an activity is

³⁸ It should be noted that, in reality, risk reductions could be the result of other activities that have a positive effect, the improvement of industry-wide data, or other factors not necessarily tied to the mitigation itself.

³⁹ The terms "pre-mitigation" and "post-mitigation" used herein (and referenced in the Settlement Decision) are not intended to suggest that all activities are Mitigations (*i.e.*, this terminology also applies to Controls).

ceased or a new activity is undertaken. The same terminology applies to the Risk Scores, which are the product of LoRE multiplied by CoRE. In short:

 $pre-mitigation risk \ score = (pre-mitigation \ LoRE) \ x \ (pre-mitigation \ CoRE)$ And

post - *mitigation risk score* = (*post* - *mitigation LoRE*) *x* (*post* - *mitigation CoRE*)

The RSE is the ratio between the pre-mitigation and post-mitigation risk scores divided by the cost. In its most simplistic form, the equation is:

simplified $RSE = \frac{(pre - mitigation risk score) - (post - mitigation risk score)}{\$ cost of activity}$

1. Illustrative Examples

Illustrative Example (One Year Mitigation)

The following is a more thorough example of a one-year mitigation. Suppose there is a risk in one Company's ERR, known as Risk X, which has been assessed using the Risk Quantification Framework. Suppose the assessment generated an assumption that a risk event related to Risk X would occur four times a year. Further, the assessment considered the potential consequences when the risk events occur. Assume, for this example, that when a risk event occurs, the assessment, consistent with methods described above, estimates a 1/10 chance that there will be four serious injuries, no reliability consequence, an average financial consequence of \$15 million to repair damage to equipment, and a statewide satisfaction score of 5.

Step 1: The first step is to formulate the pre-mitigation LoRE and CoRE. In this example, LoRE is four, because the LoRE is the average annual frequency. To determine CoRE, the Risk Quantification Framework is applied. Key parameters from the Risk Quantification Framework discussed in the section above are in the following table:

Attribute	Measurement Unit ⁴¹	Scale	Weight
Safety	Safety Index	0-20	60%
Reliability	Reliability Index	0-1	23%
Financial	\$	\$0 - \$500M	15%
Stakeholder Satisfaction	Satisfaction Index	0-100	2%

 Table 12: Risk Quantification Framework⁴⁰

Step 2: Applying the formula explained in the section above, CoRE could be calculated

$$CORE = \left[\frac{0.1}{20}\right] x \ 60\% + \left[\frac{0}{1}\right] x \ 23\% + \left[\frac{\$5}{\$500}\right] x \ 15\% + \left[\frac{5}{100}\right] x \ 2\% = \ .0055$$

Step 3: The final step is to multiply by 100,000, as discussed above, for readability purposes. Therefore, the pre-mitigation risk score is:

Suppose now that there is a proposed activity that will help reduce risk associated to Risk X. Perhaps the activity is replacing older equipment with newer equipment. Assume that, based upon data, it is estimated that undertaking the proposed activity will reduce the likelihood of Risk X occurring by 25%. In this example, the LoRE would therefore change from four to three. This activity, however, is not believed to affect the consequence if the risk event were to occur, so the CoRE stays the same.

Therefore, the post-mitigation risk score would be:

as:

post – mitigation risk score = (post – mitigation LoRE) x (post – mitigation CoRE) x 100,000 = 3 x .0055 x 100,000 = 1,650

⁴⁰ As discussed in the section above, because of the wide range of possible choices available to each utility in assigning attributes, weights, scales, and other variables chosen through implementing the Settlement Decision, the Companies provide a range of scoring, based upon two additional alternative Risk Quantification Framework methods.

⁴¹ "Measurement Unit" as used herein is the measured attribute, also analogous to "Natural Unit" per the Settlement Decision Lexicon included in D.18-12-014 at Attachment A, A-3.

Suppose the useful life of this activity is for one year, and that it costs \$10 million to perform. The RSE calculation would therefore be:

$$RSE = \frac{(pre - mitigation risk score) - (post - mitigation risk score)}{\$10M} = \frac{2200 - 1650}{\$10M}$$
$$= \frac{550}{\$10M} = 55$$

Illustrative Example (One Year Control)

A similar process is used when Control activities are considered. One important distinction for such situations is that, in the RAMP Reports, when considering the change in risk score if a control were no longer in place, the difference between the pre-mitigation risk score and the post-mitigation risk score will still be shown as a positive number because the cost of the activity in the denominator would be savings. For consistency, in the RAMP Reports, both the numerator and the denominator will be shown as positive numbers.

Suppose there is a risk in a Company's ERR known as Risk ABC and this risk has been assessed using the Risk Quantification Framework. Suppose the assessment led to the estimate that a risk event related to Risk ABC would occur once every five years. Further, the assessment estimated the consequences to be two fatalities, no reliability consequence, an average financial consequence of \$50 million to repair and replace equipment damaged by the event, and a stakeholder satisfaction score of 2.

The first step is to formulate the pre-mitigation LoRE and CoRE. In this example, LoRE is 1/5 or 0.2. To determine CoRE, the Risk Quantification Framework is applied as follows:

$$CoRE = \left[\frac{2}{20}\right] x \ 60\% + \left[\frac{0}{1}\right] x \ 23\% + \left[\frac{\$50}{\$500}\right] x \ 15\% + \left[\frac{2}{100}\right] x \ 2\% = .0754$$

For readability purposes, the utilities multiply these small decimal numbers by 100,000. Therefore, the pre-mitigation risk score is:

Risk Score = *LoRE x CoRE x*
$$100,000 = 0.2 \ x \ .0754 \ x \ 100,000 = 1,508$$

Suppose there is an activity that contributes to the risk score as it stands currently. Further, suppose there is a proposal to alter the activity in some way, such as changing the frequency of inspection. An example might be to stop a Quality Assurance program. Lastly, assume that based upon available data and subject matter expertise, it is believed that the likelihood of the risk event will be increased by 10% and save \$25 million. In this example, the LoRE would therefore change from 0.2 to 0.22 (*i.e.*, 10% more than 0.2 is 0.22). Ceasing this activity is not believed to affect the consequence if the risk event were to occur, so the CoRE stays the same.

Therefore, the post-mitigation risk score would be:

$$post - mitigation risk score = (post - mitigation LoRE) x (post - mitigation CoRE)$$

= 0.22 x .0754 x 100,000 = 1,658.8

Suppose the useful life of this activity is for one year. The RSE calculation would therefore be:

$$RSE = \frac{(pre - mitigation risk score) - (post - mitigation risk score)}{-\$25M}$$
$$= \frac{1508 - 1658.8}{-\$25M} = \frac{-150.8}{-\$25M} = 6.032$$

The Control therefore has an RSE of 6.04.

B. Duration Of Benefits

One of the more nuanced aspects of RSEs is how to address risk-reducing activities that have long-term benefits. The RSE is a comparison between performing an activity versus not performing that activity. In some cases, the implications of an activity have long term effects: pipelines last many years, computer software can be used for several years, etc. To utilize RSEs properly, some consideration needs to be given for the length of time, or duration, of predicted benefits.

A working assumption is that activities involving assets receive benefits for the life of the asset. Other activities, such as training or inspection programs, might have shorter durations of benefits. An illustrative example is a tree trimming program, which will only have a duration of benefits that match the time it takes for a tree to grow back to its former size.

Any activity that has a duration of benefits exceeding one year requires additional data points for the RSE calculation. The Example (One Year Control) above assumes that the activity has a one-year duration of benefits. However, if the assumption increased to three years of benefits, the activity can be considered to affect three years of risk results. The two tables below illustrate the resulting differences by assuming a duration of benefits for one year versus three years.

		Year			
	2022	2023	2024	2025	2026
Risk Score with Activity	980	1078	1078	1078	1078
Risk Score without Activity	1078	1078	1078	1078	1078
Difference	98	0	0	0	0

 Table 13: Example (One Year Control)

Table 14: Example (Three Year Control)

		Year			
	2022	2023	2024	2025	2026
Risk Score with Activity	980	980	980	1078	1078
Risk Score without Activity	1078	1078	1078	1078	1078
Difference	98	98	98	0	0

As shown in these tables above, the three-year benefit stream provides more value than the one-year benefit stream. The RSE calculation needs to address these differences.

C. Discounting of Benefits

The Settlement Decision allows accounting of long-term benefits of activities but requires an extra step before inclusion into the RSE.⁴² The Settlement Decision mandates that future benefits have less value than present benefits. The Companies meet this requirement by applying a "discount" rate to the difference in the risk score. In this RAMP filing, the Companies use a 3% discount rate for purposes of determining the present value of the risk reduction benefits or numerator of the RSE calculation. As shown in the example below, this

⁴² D.18-12-014 at Attachment A, A-13 (Risk Spend Efficiency (RSE) Calculation).

discount rate lowers the benefits by 3%, compounded each year. The Companies applied a 3% discount rate based on federal recommendations.⁴³

		Year			
	2022	2023	2024	2025	2026
Risk Score with Activity	980	980	980	1078	1078
Risk Score without Activity	1078	1078	1078	1078	1078
Difference	98	98	98	0	0
Discounted Difference	98 / (1.03) = 95.1	$98 / (1.03)^2$ = 92.4	$98 / (1.03)^3 = 89.7$	0	0

 Table 15: Example (Three Year Control)

As shown in the table above, the benefit decreases from 95.1 in the first year to 89.7 in the third year. The term "Present Value" is a financial concept that can also be used when discussing the future benefits of a long-term activity. For the example above, the present value of the benefit in 2022 is 95.1. For activities that have multiple years of benefits, the simplified RSE calculation changes from:

$$RSE = \frac{(pre - mitigation risk \ score \) - (post - mitigation risk \ score \)}{\$ \ of \ activity}$$

to:

$$RSE = \frac{\sum_{i}^{L} Present Value ((pre - mitigation risk score_{i}) - (post - mitigation risk score_{i}))}{\$ of activity}$$

where *i* is the year of the project, and *L* is the duration of benefits measured in years.

D. Discounting of Costs

Similar to the discounting of benefits mentioned in the section above, the Settlement Decision requires that the cost of activities also be discounted. However, in a GRC, the

⁴³ See Centers for Disease Control and Prevention, Economic Burden of Occupational Fatal Injuries in the United States Based on the Census of Fatal Occupational Injuries, 2003-2010 (August 2017) (citing 1996 recommendation from U.S. Department of Health and Human Services Panel on Cost-Effectiveness in Health and Medicine), available at https://www.cdc.gov/niosh/data/datasets/sd-1002-2017-0/pdfs/CFOI-CostTables_Methods_DetailedDescription_Final-508.

Companies present their forecasts in base year,⁴⁴ direct constant dollars. The base year for the Companies Test Year 2024 GRC is 2021. While the Companies will be seeking approval for Test Year 2024 forecasts for O&M and 2022-2024 for capital expenditures, all these forecasts will be presented in 2021 constant dollars. These direct dollar forecasts will be converted into an overall revenue requirement through the Results of Operations (RO) model. In this RAMP Report, the Companies are presenting costs in base year, direct constant dollars, consistent with the GRC framework. As of the date of these RAMP filings, the last available year of recorded data is 2020. Accordingly, the Companies used 2020 direct, constant dollars as the basis for these RAMP Reports.

Therefore, for the purposes of the RSE calculation, the costs are effectively already discounted prior to being used in the RSE calculation. Meaning, the cost for activities with multi-year expenditures does not take into account escalation prior to their usage for RSEs. For example, suppose there was a capital project that sought \$10 million a year for all three years of the next GRC forecast period (2022 through 2024). In the RAMP and in the GRC, the Companies would present these costs as \$10 million for each year, 2022, 2023, and 2024. No escalation is shown for those years; therefore, there is no need to further discount costs shown for years 2023 and 2024. Additional information is provided in Chapter SCG/SDG&E RAMP-E.

E. Application of Risk Spend Efficiencies

The RAMP Report includes 174 activities for SoCalGas and 275 activities for SDG&E. In the RAMP filing, of the total amount of costs discussed, 90% of the SoCalGas costs have RSEs performed, and 89% of the SDG&E costs have RSEs performed. RSEs were calculated for a wide variety of activities, including all in-scope non-mandated activities, certain mandated Controls, and all Mitigations whether they were mandated or not. RSEs were calculated for all non-mandated activities and all new activities.

Despite best efforts, in the development of particular RSEs for the many Mitigations and Controls in this RAMP Report, the Companies discovered that, in certain situations, RSEs could not be reasonably calculated in certain circumstances or were of minimal value. These situations include the following.

⁴⁴ The term "base year" refers to the last recorded year available prior to a GRC filing.

RSEs can be difficult to accurately determine where there is mandated work that is difficult to separate from other work. For example, when a particular regulation has been in place for decades, it is difficult to separate how the Control activity implemented to comply with the regulation would impact the likelihoods and consequences of risk events. It is difficult to unravel the value of that Control to determine quantitatively the benefits it currently gives, especially in any meaningful way.

It can also be difficult to calculate an RSE in circumstances where non-risk-reducing activities enable risk-reducing activities. For example, line inspections do not, by themselves, reduce risk directly, but they do provide information to operators and field personnel, which is then used to find appropriate remediations where necessary. Inspections are bundled together with their remediations, when calculating RSEs.

These above challenges are both present in the case of foundational activities. As described in this RAMP Report, foundational activities include activities prudent to the operation of the gas and electric system, where not performing them would not be an option for the Companies. Some examples of foundational activities are purchasing and employing the computers and vehicles that workers use to perform their job functions. It would be exceedingly difficult to determine how an enterprise risk score would change, along with changes to these types of activities.

The calculation of RSEs in this RAMP Report represents the Companies' best efforts and is in compliance with the Settlement Decision. The methodologies and processes herein have advanced the RSEs. As further discussed in section F below, RSEs should be considered as a single data point, rather than the sole source for risk-based decision-making.

F. RSE Shortcomings

Conceptually, RSEs could be a useful tool to assist in decision-making, and SoCalGas and SDG&E generally support their use and refinement. However, since they were first suggested to the Commission, RSEs have had critical shortcomings – shortcomings that continue with their most recent iteration. Because of these deficiencies (both continuing and those more recently identified), RSEs remain a data point for utilities to consider, but not the deciding factor for mitigation selection.⁴⁵ Below (in no particular order) are several of these shortcomings.⁴⁶

Lack of data: The foundation of the RSE process is the availability of broad, accurate data for every risk and mitigation. Without such data, RSEs become drastically devalued by uncertainty. To properly calculate an RSE, as required by the Settlement Decision, there must be a unique measure of the frequency and consequences of a risk, the effects of a mitigation on both the frequency and consequence of a risk, and the cost required to implement the mitigation. The problem is that for many risks and mitigations, such data is scant or incomplete. For example, the Commission requires the Companies to inspect their systems annually, but there has been little data as to how many incidents were avoided through such annual inspections.

Nevertheless, if an anomaly is observed during an inspection, the Companies would respond as needed. While the Companies may capture additional information during an inspection, the data may not always be useful for risk reduction analysis. Therefore, the Companies cannot accurately determine the risk reduction benefit associated with annual inspections at this time. This issue is further complicated where a particular control has been done for decades. All of the utilities and the Commission's staff have acknowledged the challenge with this dearth of data.⁴⁷

Another challenge commonly experienced with data is determining which data is most appropriate. Although utility-specific data is best, it is not always available. For example, for an asset-based risk, the nationally-relied upon data could be based on a utility that had not invested as much in the safety of its infrastructure. But, at the same time, the utility's infrastructure may

⁴⁵ California Public Utilities Commission, *Risk and Safety Aspects of Risk Assessment and Mitigation Phase Report of Pacific Gas & Electric Company* [PG&E] *Investigation 17-11-003* (March 30, 2018) at 35 (In their review of PG&E's RSE methodology, Safety and Enforcement Division (SED) agreed that RSEs were not the only factor for consideration in selecting mitigations.).

⁴⁶ Although the issues discussed in this section were discussed in the last RAMP Reports, they are included here in somewhat streamlined form because they persist.

⁴⁷ See Investigation (I.)16-10-015/-016 (cons.), Order Instituting Investigation Into the November 2016 Submission of San Diego Gas & Electric Company's Risk Assessment and Mitigation Phase (October 27, 2016), I.17-11-003, Order Instituting Investigation into the November 2017 Submission of Pacific Gas and Electric Company's Risk Assessment and Mitigation Phase (November 9, 2017), and I.18-11-006, Order Instituting Investigation into the November 2018 Submission of Southern California Edison Risk Assessment and Mitigation Phase (November 8, 2018).

be less likely to experience risk events for other reasons, such as population densities, the environment, or other factors. It is difficult to balance all of these factors with precision.

<u>Frequency of Incidents</u>: Related to the previous point, the lack of the availability of data is difficult to overcome in some instances, because of the infrequency of incidents for many risks. This is particularly the case with "tail" risks. Tail risks are those risks that occur very infrequently, finding themselves on the very extreme end of a probability curve (*i.e.*, the "tail"). Understanding the reduction in risk associated with infrequent catastrophic incidents is difficult to determine because of the frequency of events.

<u>Reliance on Subject Matter Experts (SMEs)</u>: The lack of available data and frequency of tail risks leads to a reliance on SMEs to assess how much a risk will be reduced by the implementation of a mitigation and requires SMEs to determine whether the available data is appropriate and applicable to our operations. As the Commission's Safety Division has acknowledged, the RSE is a product of SME input.⁴⁸ Although SMEs can be a strong source of input, they can benefit from quantitative calibration. It is frequently beneficial to train SMEs how to think quantitatively and to perform "sanity checks" on their input, by considering scenarios to truth test their inputs. As a result, RSEs are subject to the potential issues that can occur when SME input is used without calibration, or without consistent care in how SME input is scrutinized.

<u>Changes Occur</u>: Conditions change over time. Consequences and frequencies of events, priorities for the Commission and utilities, and other important factors in decision-making can change, even within a rate case cycle. As a result, predictive RSEs can be of limited value and fairly speculative. One of the clearest examples of this is found when calculating RSEs for vegetation management mitigations. In such calculations, one cannot reasonably account for changes in growth rates, costs or even fluctuations in weather. The type and growth rate of vegetation can change in an area; unpredicted weather patterns can change the biological and geographical landscape. RSEs can therefore vary widely from forecast to reality. The Commission appears to recognize this, as evidenced by its acknowledgement that utilities require flexibility to adapt to changing conditions and in addressing risk.

⁴⁸ California Public Utilities Commission, *Risk and Safety Aspects of Risk Assessment and Mitigation Phase Report of San Diego Gas & Electric Company and Southern California Gas Company Investigation* 16-10-015 and I.16-10-016 (March 8, 2017) at 16.

<u>Changing Methodologies and Tools</u>: Comparing past and future RSEs, even from one cycle to the next, is generally of limited value. Changes will occur in methodologies and tools over time. This is recognized in D.18-12-014, which notes that utilities' MAVFs will evolve over time.⁴⁹ This evolution can take many forms. It can result from simply refining data, but wholesale changes to the structure of the Companies' Risk Quantification Framework may also occur. As a basic example, in this RAMP cycle, the Companies have added a fourth attribute and a sub-attribute for SDG&E's reliability MAVF. These and future changes make comparing RSEs across cycles of limited value.

<u>Non-RSE Factors</u>: Perhaps one of the most critical shortcomings of RSEs is that there is much they do not capture. The methodologies for determining RSEs do not take into consideration all the factors that go into the decision to select a mitigation. For example, if a utility intends to replace a bare wire conductor with insulated conductor, the RSE calculation will consider the risk reduction achieved by installing the new conductor and the cost of the new conductor. While factors such as resource availability, permitting requirements, and changing climate conditions are not considered within the RSE calculation, these factors are certainly taken into consideration for decision-making purposes. Similarly, certain human factor benefits, such as those related to training and communicating with the public, are not easily captured as part of the RSE calculation.

<u>RSEs Cannot Be Compared Across Utilities</u>: RSEs cannot be compared in a meaningful way across utilities. Although the Commission and Intervenors have previously expressed a desire for RSE comparability across utilities on similar risks or mitigations, that is not possible at this time.⁵⁰ Each of the utilities use different formulas and methodologies in calculating RSEs. Each utility might use different attributes, different weights and scaling, and even different frequency and consequence valuations.

Lack of Common View of Risk Tolerance: There is no shared viewpoint on risk tolerance. The Commission's Safety Division, individual intervenors, and a utility may have different views regarding the permissible number of incidents on a particular system. Some

⁴⁹ D.18-12-014 at 54.

⁵⁰ See D.16-08-018 at 164.

might say they want zero incidents while others may say there should be no incidents beyond a certain size. These varying tolerances lead to different mitigations and RSEs. In addition, certain outcomes may be a higher priority to avoid because of their cause – but RSEs cannot capture that type of preference. As noted in RAMP-E, the Commission is considering whether to adopt a risk tolerance standard as a statewide issue in the ongoing S-MAP OIR.⁵¹

Mitigation Synergy not Recognized: As the MAVF for creation of RSEs currently stands, it is incapable of accurately determining the value of RSEs when mitigations are combined or broken up. Some mitigations work best when combined with one or more mitigations. Because RSEs must presented as standalone scores, the value of combining RSEs cannot be captured. Similarly, some mitigations apply across multiple risks. The RSE calculation methodology as it currently stands does not allow for a clear recognition of such benefits. Although combining the benefits across all risks impacted improves accuracy, doing so would significantly add to the complexity of the analysis and presentation of the mitigation benefits. For example, the replacement of live front equipment mitigation impacts both the Electric Infrastructure Integrity (EII) risk and the Employee Safety risk. However, the Companies elected to assess the mitigation benefit as part of the EII risk to minimize double counting of benefits throughout this 2021 RAMP Report. Thus, the risk reduction within the Employee Safety risk is underestimated since the mitigation was assessed against the EII risk. This is another instance of RSEs not being able to capture the entire picture when it comes to the costs and benefits of mitigations or controls.

<u>Non-Asset Mitigations/Controls</u>: Non-Asset mitigations may also not lend themselves well to evaluation by RSEs. Because some Non-Asset mitigations cannot always be broken down into relevant, discrete data points, trying to force them into a quantitative analysis is challenging. For example, consider the benefit of training. It is difficult to ascertain the precise amount of impact a training program has. The simplest way is to attempt to compare results with and without a program. But there are likely other changes occurring within a risk, and knowing which factor contributed to a change in risk outcomes is difficult. Consider driver training for employees. All employees who exceed a certain number of driven miles using company vehicles are required to take driver training. Simultaneously, improvements to vehicles have been made,

⁵¹ See Rulemaking (R.) 20-07-013, Assigned Commissioner Scoping Memo and Ruling (November 2, 2020) (S-MAP OIR Scoping Ruling) at 7-9.

such as the installation of back-up cameras. It is very difficult analytically to say whether an incident did or did not occur due to the training or the installation of equipment. There are a substantial number of mitigations that utilities pursue and implement that are not asset-based. Determining how to assess them within an RSE-driven framework continues to be problematic.

<u>RSEs Do Not Reflect the Reality of Utility or Commission Priorities</u>: Capturing actual or strategic priorities when valuing mitigations is a challenge. Although there are several shortcomings in the RSEs that are primarily data driven, one of the most challenging to quantify is related to valuing mitigations that are strongly supported by the Commission and IOUs' strategic efforts and priorities. Certain mitigations are recognized by essentially all interested parties to be important – yet their RSEs would suggest they should be treated as lower priority work. For example, in the high-pressure pipeline incident risk, the valve automation mitigation had a relatively low RSE, yet valve automation was required by the Commission in D.14-06-007.⁵² The rankings of RSEs shown in Appendix C-1 contain other examples of these types of mitigations.

⁵² D.14-06-007 at 21.
